Life Cycle Assessment of Disposable and Reusable Nappies in the UK

The project was informed and assisted by an Advisory Board set up by the Environment Agency. Membership of the Advisory Board was decided by the Environment Agency on the basis of interest, balance and ability to assist in data collection.

The Advisory Board members were:

- Stewart Begg Absorbent Hygiene Product Manufacturer Association (AHPMA);
- Terry Coleman (*Chairman*) the Environment Agency;
- Geoff Davies Swindon Unitary Authority;
- Joanne Freer Cotton Bottoms;
- Dr Ioannis Hatzopoulos Procter & Gamble Service GmbH;
- Ann Link Women's Environmental Network;
- Joanna Marchant the Environment Agency;
- Gillian Neville Defra;
- Vicki Portman Plush Pants (one meeting); and
- Gina Purrman Real Nappy Association.

The Environment Agency is the leading public body protecting and improving the environment in England and Wales.

It's our job to make sure that air, land and water are looked after by everyone in today's society, so that tomorrow's generations inherit a cleaner, healthier world.

Our work includes tackling flooding and pollution incidents, reducing industry's impacts on the environment, cleaning up rivers, coastal waters and contaminated land, and improving wildlife habitats.

This report is the result of research commissioned and funded by the Environment Agency's Science Programme.

Foreword

Even though we now recycle nearly 18 % of our 25 million tonnes of household waste we still landfill the majority of the remaining waste. We need to continue with the programme of actions to deliver much greater recovery and reuse of these materials.

As we re-examine the impacts of what we produce, and the waste we generate we need a framework to decide what makes sense. That is where Life Cycle Assessment (LCA) can be used. It forces a rational examination of all the environmental impacts of products and services.

2-3% of our household waste is estimated to be disposable nappies, approximately 400,000 tonnes of waste each year.

The alternative is to use reusable nappies. This reduces demands on landfill but reusable nappies impact on the environment in other ways such as the water and energy we use in washing and drying them. Both approaches therefore create their own environmental impacts.

This study reported on the way people used the leading types of both disposable and reusable nappies in 2002/3. As new products come onto the market place we will update this study and already plan to review the next generation of nappies. We expect those developing these products to use this study to shape more sustainable designs of nappies.

These are steps forward but we still need to tackle the volume of disposable products that go to landfill. If we take the Government's most optimistic forecasts we will still be landfilling over 350,000 tonnes of disposable nappies. This is at a time when we aim to reduce the volume of biodegradable waste going to landfill and to deliver more sustainable waste management. Therefore we want the main manufacturers of disposable nappies to work with us to find ways to reduce the volumes that go to landfill.

We also look to reusable nappy manufacturers to help parents review the way they launder and dry reusable products to reduce their water and energy impacts.

This LCA study provides the framework against which we can judge the success or failure of actions to reduce the impacts of reusable and disposable nappies. Further information on this study and on how you can reduce environmental impacts from the use of reusable and disposable nappies and related products is on our website at <u>www.environment-agency.gov.uk</u>

Director of Environmental Protection

Executive Summary

In recent years, there has been considerable debate over the relative environmental performance of reusable (cloth) nappies and disposable nappies. While many people intuitively think that reusable nappies are better for the environment, disposable nappies account for some 95 per cent of the market and around 2.5 billion disposable nappies are sold in the UK each year.

The environmental impacts of different nappy types have been investigated in numerous studies. However, these studies have been limited in their accuracy or in their scope and have often been carried out by, or on behalf of, an organisation with a vested interest in the study results.

In 2001, the Environment Agency commissioned the environmental consultancy Environmental Resources Management Limited (ERM) to provide an independent and objective environmental life cycle assessment of nappy use in the UK. Life cycle assessment (LCA) is a technique used to assess environmental performance over the entire life cycle, from raw material extraction through to product manufacture, use and final disposal.

The study reported here complies with the latest methods laid down in international standards (ISO14040).

Study aims

The aim of the LCA study was to assess the life cycle environmental impacts associated with using disposable nappies and reusable nappies in the UK for 2001-2002. Three different nappy types were assessed:

- disposable nappies;
- home laundered flat cloth nappies; and
- commercially laundered prefolded cloth nappies delivered to the home.

The systems studied

To compare the nappies fairly, the study considered the environmental impacts associated with an average child wearing nappies during the first two and a half years of its life. For each nappy type studied, all the materials, chemicals and energy consumed during nappy manufacture, use and disposal, and all the emissions to the environment were identified. All these 'flows' were quantified and traced back to the extraction of raw materials that were required to supply them. For example, polymer materials used in disposable nappies were linked to the impacts associated with crude oil extraction and the flows associated with the fluff pulp used in disposables were traced back to paper and forest growth. For cloth nappies, the flows were traced back to cotton growth and production. All transport steps have been included.

The environmental impact categories assessed were those agreed by the project board: resource depletion; climate change; ozone depletion; human toxicity; acidification; fresh-water aquatic toxicity; terrestrial toxicity; photochemical oxidant formation (low level smog) and nutrification of fresh water (eutrophication). These environmental impacts were calculated for an average nappy system in each case. The study therefore excluded impacts such as noise, biodiversity and the amount of land used by each system.

The total flows of each substance were compiled for each stage of the life cycle and used to assess the environmental impacts of each system. For example, flows of methane, carbon dioxide and other greenhouse gases were aggregated for each system in total. Internationally agreed equivalents that quantify the relative global warming effect of each gas were then used to assess the overall global warming impact of each nappy system. *Figure 1* shows the system that was studied for commercially laundered cloth nappies.

For the three nappy systems, manufacturers provided data for their production processes. Commercial laundries also supplied data. Published excreta data was used for the contents of used nappies. Data on the numbers of different nappies in use and how they were washed etc. were estimated from surveys undertaken for the Environment Agency ⁽¹⁾. Published life cycle inventory data were used to describe commodity material and energy inputs to the stages.

Sensitivity analyses were conducted for the following key areas of uncertainty:

- reusable nappy manufacture;
- aquatic toxicity impact method;
- drying methods for reusable nappies; and
- how excreta were disposed of.

⁽¹⁾ Environment Agency, 2004 *Time to change? A study of parental. habits in the use of disposable and reusable nappies.* Environment Agency.

Figure 1 Commercially laundered cloth nappies

Conclusions

For the three nappy systems studied, there was no significant difference between any of the environmental impacts – that is, overall no system clearly had a better or worse environmental performance, although the life cycle stages that are the main source for these impacts are different for each system.

The study was supported by a stakeholder group representing the interested parties and is the most comprehensive, independent study of its kind. It should be used as the basis for any further studies comparing the impacts of different types of disposable or reusable nappies.

The most significant environmental impacts for all three nappy systems were on resource depletion, acidification and global warming. For one child, over two and a half years, these impacts are roughly comparable with driving a car between 1300 and 2200 miles.

The study has been critically reviewed by an external expert appointed by the Environment Agency. The review and how its findings were addressed is included in the report.

1 Introduction

1.1 Project background

There has been considerable debate about the relative environmental impacts of reusable and disposable nappies, and a number of life cycle assessment (LCA) studies have been carried out on this topic since the mid-1970s. These predate the publication of ISO14040; the International Standard for LCA. Many of the studies conform to the principles of ISO 14040, but it is generally felt that they do not represent the present UK situation due to the age of the studies and developments in the design, manufacture and use of both disposable and reusable nappies.

The Environment Agency is an independent organisation and has commissioned this LCA study to provide an accurate and objective assessment of the environmental impacts of the production, use and disposal of reusable and disposable nappy systems for the UK as a whole.

Over the last two decades, disposable and reusable nappy systems have been subject to numerous life cycle studies (see *Section 11.1* for a list of previous studies). Since they were conducted, ISO guidance has been published and new methodologies for impact assessment have been developed. Previous studies have been limited in their scope, both in the life cycle stages addressed and in the environmental issues assessed; the majority being limited to inventory analysis or analysis of specific burdens and not including a full range of environmental impacts.

This study does not assess individual brands.

The specific objectives of the project, specified by the Environment Agency, were:

- to compile a detailed life cycle inventory of the environmental burdens associated with the production, use and disposal of reusable and disposable nappies, considering various options for cleaning reusable nappies, and for disposing of disposable nappies;
- to use the life cycle inventory data to compare the potential environmental impacts arising from reusable and disposable nappies under the various scenarios considered; and
- to compare the results of the study with other key life cycle studies in this area and to identify the main reasons for any significant differences⁽²⁾.

⁽²⁾ This objective was considered superfluous due to the developments in LCA methodology, with nappies themselves and because the study is UK specific.

1.2 Life Cycle Assessment

The international standard for Life Cycle Assessment, ISO14040 (ISO, 2000), states that: *"LCA is a technique for assessing the environmental. aspects and potential. impacts associated with a product by:*

- compiling an inventory of relevant inputs and outputs of a product system;
- evaluating the potential. environmental. impacts associated with those inputs and outputs; and
- interpreting the results of the inventory analysis and impact assessment phases in relation to the objectives of the study."

LCA studies the environmental aspects and potential impacts throughout a product's life (i.e. from cradle to grave), from raw material acquisition through production, use and disposal. The general impacts needing consideration include resource use, human health, and ecological consequences.

The key elements of an LCA are:

- goal and scope;
- life cycle inventory analysis;
- life cycle impact assessment;
- life cycle interpretation;
- · reporting; and
- critical review.

1.3 About children and nappies

Nappies are used to absorb and contain excreta produced by small children. The nappies that are used today in the UK fall into two distinct groups, disposables and reusables. These two forms, although fulfilling essentially the same function, are fundamentally different in nature and in use. Disposable nappies are single use items with no requirement for folding/preparation and no need for washing. Once used, the nappies containing excreta are generally thrown away with other household waste. Reusables are generally made of cotton cloth and are laundered and re-used many times. Excreta from these is predominately treated by the sewerage system.

It is in the first 2.5 years of life that babies are heavily dependent on nappies. After this period, children are generally less dependent on nappies due to potty training, with nappies being used mostly at night, if at all.

1.3.1 Excreta volumes

By 2.5 years, approximately 90 per cent of girls and 75 per cent of boys have complete bladder control (Stoppard, 1990). The average child will stay dry at night at 33 months (normal range 18 months to 8 years) (Green, 1998). During the first 2.5 years, according to Geigy *et al.* (1981), approximately 254 litres of urine and 98 kg of

faecal matter are produced (Lenter, 1981), see *Table 1.1* and *Table 1.2*. Geigy *et al.* is a comprehensive publication in terms of volumes, composition and referencing.

Forfar and Arneil's Textbook of Pediatrics (1998), although not as comprehensive in its references as Geigy, suggests a range in urine volume of approximately 409 to 506 litres, and a range in faecal mass of 6.9 to 48.4 kg over 2.5 year period, see *Table 1.5, Table 1.6, Table1.7* and *Table1.8*. An alternative data set published by Goellner *et al.* (1981) suggests that 633 litres of urine are produced during the first 2.5 years, see *Table 1.3* and *Table 1.4*. Potty training is a variable that is difficult to include in the study, as it is extremely child dependent. Potty training will affect the use of nappies by a child and the disposal routes for excreta.

There is limited scientific literature regarding the excreta produced by children. Although quantities are of interest, in terms of the environment, composition (see *Table 1.9, Table 1.10, Table 1.11* and *Table 1.12*) and destination are likely to be of more significance.

If we use the Geigy data, in 2001-2002, 172,000 tonnes of urine and 66,000 tonnes of faecal matter would be produced by nappy wearing children (1.69 million children). If we use the Forfar data, in 2001-2002, 276,000 to 342,000 tonnes of urine would be produced by nappy wearing children.

There are other differences between the data from Geigy, Forfar and Goellner. The Geigy data includes urine, faeces and composition data, unlike Goellner, which addresses only urine volume. The Forfar data addresses urine and faeces volume, but includes more limited composition data. The Forfar faeces data is more limited than Geigy, though the data is from the same source. The Geigy faeces data seems to be the most comprehensive.

In this study, the volume of excreta generated is varied to reflect the range in the generation rates and the difference in the excreta that is captured within nappy systems. Two scenarios were analysed, one using Geigy data and the other using a mixture of Forfar data for urine and Geigy data for faeces.

1.3.2 Disposables

Disposables can be divided into the following categories:

• the super-absorbent nappy (ultras); and

• **the basic nappy** (no super-absorbent polymer, relying on fluff pulp for absorbency).

Ultras are the dominant type of disposable nappy on the market in terms of sales, accounting for 94 per cent of the market in 1999 (MINTEL, 2000). Disposable nappies are sold in a number of sizes for different weights of babies, the most popular size range being for babies between 20 and 40 lbs in weight (MINTEL, 2000). The basic nappy is considered a niche market as none of the major manufacturers produce these nappies and it is therefore not representative of the market.

1.3.3 Reusables

Today's reusable and washable cotton nappies come in a variety of forms and are nearly all fitted and fastened with poppers or velcro straps instead of pins. There are many different reusable nappy systems, which can be divided into the following broad categories:

- **all-in-ones** shaped, fitted nappies with velcro or popper fastenings, which have a built-in waterproof cover. No folding or pinning is required;
- **shaped nappies** similar to all-in-ones, but *without* the built-in waterproof cover which is purchased separately (wraps/pants). These do not require folding. They are fastened by velcro or poppers; and
- **flat nappies terry/wrap around/prefold** require folding and a separate waterproof wrap/pant, with fasteners used in some cases.

All-in-one nappies are similar in appearance to disposable nappies, comprising an absorbent layer with an integral waterproof wrap/pant. They are usually fastened with velcro. They are slower to dry because the waterproof layer reduces drying efficiency.

Shaped nappies are generally considered easier to use than flat/prefold nappies, in that no folding is required. Some have velcro or popper fastenings, and others rely on the wrap/pant to hold them in place.

Terry nappies are made of 100 per cent terry towelling squares. Terries can be folded in a number of ways to suit different size babies. Terries are considered to be quick drying.

Prefold nappies are made from woven cotton and consist of a large rectangle of fabric that has been folded and stitched into three panels, the centre panel being thicker than the two outer panels. Prefolds are considered quick drying.

Traditionally, terries were fastened with safety pins, but plastic grips/wraps/pants are now generally used to fasten terries. Prefold nappies are designed to be used without fasteners and are held in place by the wrap/pants.

1.3.3.1 Wraps/Pants and liners

Wraps/pants are made of a number of different materials and combinations of materials, such as: nylon; polyvinyl chloride (PVC); ethylene vinyl acetate (EVA); polyester; cotton; wool; hemp; and polyurethanes. Wraps/pants are not considered as durable to washing, drying and wear as nappies, and hence they may need to be replaced at regular intervals. Wear is dependent on the care they receive. Following manufacturers' care guidance is essential for maximising their life. Some wraps/pants are adjustable and are designed for use from birth to potty; others are replaced when necessary to fit a growing baby. Generally, three different sizes will be needed over the period of a baby's use of nappies.

In combination with the nappies and wraps/pants, parents can use liners and booster pads to improve performance and ease of cleaning. Liners are used to provide a drier layer between the baby and the absorbent nappy, to assist in containment of faecal matter and for ease of cleaning. Liners come in reusable or disposable forms. Materials that are used include paper, polypropylene, fleece and silk. Depending on circumstances and on the baby, it is sometimes necessary to boost the performance of a nappy by doubling up nappies to increase absorbency or to use specifically manufactured booster pads.

1.3.4 Market share

There are three main manufacturers and suppliers of disposable nappies in the UK: Procter & Gamble; Kimberly Clark; and SCA Hygiene. Together with other smaller brands of disposable nappies, the total number of disposables sold annually in the UK is approximately 2.47 billion (Absorbent Hygiene Products Manufacturers Association (AHPMA)). At an average weight of 44.6 g (UK average weight, 2001), this would equate to a total sold of approximately 110,000 tonnes per annum that will become waste after use (not including excreta). Together, Procter & Gamble and Kimberly Clark account for approximately 75 per cent of the market and SCA account for most of the rest (MINTEL, 2000). Both Kimberly Clark and Procter & Gamble manufacture disposable nappies in the UK, whilst SCA manufactures nappies on mainland Europe.

Although no published market data has been found, various informed views refer to a market penetration for reusables of between 5 per cent and 15 per cent of babies (Environment Agency, 2004). However, recent research by the Environment Agency determined market share to be less than 4 per cent (Environment Agency, 2004). There has been an expansion in the number of suppliers in the UK over the last few years, which may suggest the market share is growing.

The major retail routes for reusables appear to be through high street shops, mail order, via the internet and from nappy sales agents, while a nappy home delivery and collection service is provided by nappy laundries (effectively nappies are rented on a weekly basis).

Commercial nappy services that involve a centralised laundry are gaining in popularity and coverage in the UK. A bin is provided by the laundry service for the collection of dirty nappies and for the delivery of washed and dried nappies on assigned days.

1.4 Previous studies

Previous studies provide us with an indication of the significance of the various life cycle stages and the critical issues that affect the results of an LCA study of nappies.

For both disposable and reusable nappies, raw material production and manufacturing have been identified as significant aspects of the life cycle. For disposables, it has been suggested that end of life is significant. For reusables, the use stage has been identified as significant due to the energy, detergent and water requirements of laundering operations and the subsequent treatment of wastewater.

Omissions from previous studies include the environmental impacts of waste disposal, both solid and liquid wastes, and retail and consumer transport steps.

The main issues that have been identified from previous studies as having a significant influence on results are:

- the daily number of changes for each system;
- the number of reusable nappies required over a given period;
- consumer care parameters (washing temperatures/wash loads/wash frequency/drying method/detergent loading etc.);
- reusable nappies are sometimes doubled up to provide sufficient absorbency; and
- reuse assumptions for reusables once they are no longer required by the child.

Previous studies have provided data regarding the daily consumption of disposable and reusable nappies during the period in which a child is in nappies. The number of disposable nappies used per day in the previous studies (see list in *Section 4.1*) ranged from 4 to 6.4 as an average for the 2.5 year period. The corresponding range for reusable nappies is 5.8 to 12.2.

When determining the number of nappy changes per day, a number of different factors must be taken into account. The age of the child will be a key determinant of the number of changes, as a younger child is generally changed more frequently than an older child. Disposable nappies, due to the absorbency of fluff pulp and sodium polyacrylate (super absorbent polymer or SAP) can contain large volumes of liquid. This absorbency is reflected in the lower change frequency that is reported for disposable systems when compared with reusable systems. To increase absorbency at night time, a reusable nappy may be used with a booster pad or another nappy, although this is dependent on the type of reusable nappy. Consequently, the total number of nappies used per day may be lower for the disposable system.

In previous studies, the manufacture of disposables is well reported and quantified. However, there is a lack of data regarding cotton production and reusable nappy manufacturing. For disposable nappies, there is a lack of data describing the behaviour of disposable nappies and their contents when they are disposed. For reusable nappies, there is a lack of data regarding the management of the excreta at waste water treatment plants. This study aimed to obtain data to fill these gaps and to obtain new and up to date information regarding consumer use characteristics in the UK. The study also addresses, through sensitivity analysis, critical assumptions for which data are not available. The study includes all life cycle stages and conforms to the international standards for LCA.

2 Goal of the study

The international standard ISO 14041 (ISO, 1998) requires that the goal of an LCA study shall unambiguously state the intended application, the reasons for carrying out the study and the intended audience.

The goal of this study is to assess the potential life cycle environmental impacts associated with using disposable and reusable nappies in the UK in 2001-2002.

The goal of the study has been split into the following objectives:

- to compile a detailed life cycle inventory of the environmental burdens associated with the production, use and disposal of reusable and disposable nappies, considering various options for cleaning of reusable nappies, and disposal options for disposable nappies; and
- to use the life cycle inventory data to compare the potential environmental impacts arising from reusable and disposable nappies under the various scenarios considered.

The LCA study will be used to report the environmental aspects associated with the life cycles of reusable and disposable nappy systems to the Environment Agency and to a wider audience. As this study will be used externally, it has undergone critical review by an external reviewer in accordance with ISO14040.

3 Scope

The scope of the study addresses the following items:

- the functions of the product systems;
- the functional unit;
- the product systems to be studied;
- the product system boundaries;
- allocation procedures;
- types of impact and methodology of impact assessment, and subsequent interpretation to be used;
- data requirements;
- assumptions;
- limitations;
- initial data quality requirements;
- type of critical review; and
- type and format of the report required for the study.

3.1 Functional unit

Previous life cycle studies that have compared the environmental profiles of disposable and reusable nappies have used various functional units. Some of these have defined a time period while others have chosen to look at a specific number of nappy changes.

The function that is appropriate to the goals of the study is defined as "*the use of nappies during the first 2.5 years of a child's life, in the UK, for the period 2001-2002*". This functional unit will result in a specific quantity of disposable and reusable nappies used within the time period of 2.5 years.

The reason for focussing on the first 2.5 years is that by this point nappy use is tailing off, and beyond this point nappy use varies considerably between individuals. This approach takes into account the range of sizes and fluctuations in user patterns that may occur during the total period a child is in nappies.

This functional unit was agreed by the Project Advisory Board.

The Environment Agency commissioned surveys of both disposable and reusable nappy use. These surveys (Environment Agency, 2004) determined that the average child is out of nappies at 2 years 2 months (same for both type of nappy) and that after 2.5 years 95 per cent of all children are out of nappies. The study reflects the first 2.5 years of an average child's life in the UK. Therefore, the systems modelled take account of those children who stop using nappies earlier than 2.5 years, see *Table 3.1.*

The time children spend in nappies is specific to the individual, but the majority of children have undergone toilet training under the age of 2.5 years. Although they may still use training pants or overnight nappies for a significant period beyond this point, the use of these types of products is outside the scope of this study.

Age of child	Children wearing nappies (%)	Children not wearing nappies (%)
up to 6 months	100.0%	0.0%
6 to 12 months	95.7%	4.3%
12 to 18 months	82.8%	17.2%
18 to 24 months	45.6%	54.4%
24 to 30 months	17.6%	82.4%
30 to 36 months	4.8%	95.2%
36 to 42 months	1.8%	98.2%
42 to 48 months	0.4%	99.6%
48 to 54 months	0.1%	99.9%
54 to 60 months	0.1%	99.9%
60 to 66 months	0.1%	99.9%

Table 3.1Children wearing nappies by child age (all types of nappy)

Source: The Environment Agency surveys (Environment Agency, 2004) Note: The surveys showed that there is no difference in age out of nappies between children using reusable or disposable nappies. The figures in the table are for disposable nappies for which there were more results but were applied to all children.

3.2 Product systems and system boundaries

The system boundaries define the life cycle stages and unit processes to be studied and the environmental releases (e.g. carbon dioxide, methane etc.) and inputs (e.g. coal reserves, iron ore etc.) to be included in the evaluation. System boundaries should be defined in such a manner that the inputs and outputs from the system are elemental flows (3).

The aim of the study is to include all the significant processes, tracing material and energy flows to the point where material and energy are extracted or emitted to the natural environment.

The objective of the project was to assess a typical disposable and a typical reusable, taking into account 'all in one' type nappies and the flat nappies with a wrap/pant.

⁽³⁾ An elemental flow is material or energy entering the system being studied, which has been drawn from the environment without previous human transformation, or it is a material or energy leaving the system being studied, which is discarded into the environment.

It was the ambition of this study to be representative of the UK situation, in 2001-2002, and to reflect the nappies that are used in the UK. The study reflected the UK situation by assessing the average nappy systems in use in 2001-2002. By average, we mean in terms of weight, composition, manufacturing processes and use characteristics.

This study addressed flows to and from the environment for each life cycle stage. However the study excluded the environmental implications of land occupation and use, for example, the implications of alternative land use and the effects of land use changes were excluded. The systems assessed were considered to be steady state.

3.2.1 Average systems

To study average systems, a substantial amount of data and statistics for nappies used in the UK was collected to ensure that the study was representative of UK usage.

The main disposable nappies in the UK are very similar. Due to their similarities in terms of composition and use, it was practicable and reasonable to assess an average disposable nappy sold in the UK. A calculated average nappy, in terms of composition and weight sold in the UK, in a particular year, can be assumed to be an accurate representation of the nappies used by a child over its first 2.5 years of life. A methodology to specify the average disposable nappy in the UK was developed by ERM and applied by the disposable nappy manufacturers. *Table 3.2* shows the results of this process.

With regard to reusables, the picture was more varied, due to the diverse range of products and combinations (wraps/pants, liners and booster pads) in use. The lack of market data and user surveys regarding popularity made it difficult to define typical systems. As a result, ERM conducted a survey of reusable sales by nappy type in the UK in order to define an average reusable nappy for this study. The survey ascertained that the most popular type of nappy in the UK is the terry nappy, and the most popular wrap/pant is the plastic waterproof wrap/pant. Terry nappies accounted for approximately 37 per cent of reusable nappy sales, with prefolds totalling 25 per cent. Shaped and 'all-in-ones' had similar sales of approximately 20 per cent each.

The Environment Agency surveys (Environment Agency, 2004) showed that terry nappies were the most popular and prefold nappies a close second amongst the survey population. 'All-in-ones' were by far the least popular.

On the basis of these surveys, it was agreed that both terry and prefold nappy systems should be studied.

The surveys undertaken on behalf of the Environment Agency also provided data on how nappies are used and cared for, the use of liners and booster pads, the number of changes and the types of wraps/pants and waterproof pants used.

The survey identified that terry users own on average 31.2 nappies at any one time. However, the survey failed to ascertain how many were purchased in total, by users, over the 2.5 years. We have assumed that the maximum owned in any one six month period reflects the total purchased. This equated to 47.5 nappies. This figure is not considered to be robust due to the limited number of data points, but it is believed to be reasonable when one considers that 31.2 terry nappies are owned at any one time. The majority of users do not use booster pads but do use disposable liners. 88 per cent of reusable nappy users use disposables as well as reusables. The most popular wraps/pants amongst terry nappy users were PVC wraps.

The nappy systems assessed include all life cycle stages. All energy and materials used were traced back to the extraction of resources. Emissions from each life cycle stage were quantified. Waste management processes (landfilling, incineration and waste water treatment) were also assessed.

The Environment Agency surveys of consumer use have been used to define the nappy systems modelled (Environment Agency, 2004).

3.2.2 Disposable nappy system

Most of the disposable nappies that are sold in the UK are also manufactured in the UK, although several raw materials are obtained from other European countries or from North America.

Disposable nappies are based on two main materials; cellulose fibres and polymers. The core is composed of fluff pulp and SAP, which is a water absorbing polymer. The function of the core is to absorb and contain liquid excreta. The top layer, referred to as 'non-woven', is a polymer-based material with a textile structure. From the top layer, the fluids flow through a pulp-based tissue layer down to the core. Leakage is minimised by a plastic bottom layer and by elastic barriers. The nappy is prevented from falling off by rubber waist elastics and is fastened around the child's waist by non-woven based hook and loop details.

The different materials in the nappies are glued together with polymer-based adhesives. The packaging consists of polyethylene plastic bags and corrugated board boxes. Nappies are sold in different pack formats, of which the convenience pack (one week's supply), the economy pack (2 weeks' supply) and the Quattro pack (3 weeks' supply) are the most common.

Table 3.2 presents the average composition of a UK disposable nappy for 2001-2002. *Table 3.3* presents the average composition of European disposable nappy in 2000.

Table 3.2Average UK disposable nappy composition and weight (2001-2002)

Average wt	Fluff Pulp	SAP	LDPE	PP	Elastic	Adhesives	Other
g	%	%	%	%	%	%	%
44.64	42.77	27.63	7.74	15.25	0.53	2.99	3.09

LDPE: Low Density Polyethylene PP: Polypropylene

Nappy Component	Details	Composition
Core	Consists mainly of fluff pulp (43% of a nappy) and super absorbent material (27% of a nappy). Absorbance and retention of urine.	70%
Polypropylene	Polypropylene topsheet protects skin from wetness	10%
Polyethylene	Polyethylene backsheet provides leakage protection	13%
Other	Consists of tapes, elastics and adhesives	7%
TOTAL		100%
Average weight of a nappy		45-50 g

Table 3.3Average European (UK included) disposable nappy composition(2000)

Source: EDANA, 2001.

The nappies are distributed from the manufacturers either directly to retailers (grocery/supermarket chains, independent grocers or chemists), or via distribution centres maintained by the manufacturers. Customers buy their nappies at the retailer and transport them home for use. Used nappies (containing excreta) are discarded along with other municipal waste and will later on end up disposed either to landfill or to incineration. In the UK, approximately 8 per cent of municipal waste is incinerated.

Figure 3.1 details the main life cycle stages that will be included in the life cycle of disposable nappies. Due to the complexity of the product system, it is impractical to draw a full system diagram that includes all the processes where human influence occurs, although they have been included in the study.

Figure 3.1 Outline system diagram for the disposable nappy system

3.2.3 Home laundered reusable nappy system

Figure 3.2 details the main life cycle stages that have been included in the life cycle of home laundered reusable nappies. Due to the complexity of the systems reported in the surveys, a terry system has been defined according to the dominant use characteristics identified in the surveys, this system has then been tested through a number of scenarios (developed from the survey) in sensitivity analysis.

Most of the terry nappies that are sold in the UK are believed to be manufactured outside of the UK, in areas associated with cotton growing and textile production such as Pakistan, China and the USA. However, there are terry nappy manufacturers in the UK.

Cotton is a perennial crop, with mature cotton bolls harvested mechanically and transported to a ginning plant where the cotton fibre is separated and baled. The cotton bales are then transported to textile manufacturers or yarn spinning plants, where they are opened, the cotton fibre is carded and spun into yarn. The yarn is then woven into terry towelling, cut and stitched. The nappies are then packaged and dispatched to customers.

Consumers purchase the terry nappies and associated accessories, such as wraps and liners, from retail outlets such as supermarkets, high street stores, chemists and via the internet.

During use, terry nappies are generally soaked in a solution of sanitising fluid prior to washing. Nappies are washed in washing machines and either tumble dried or air dried.

The bins used for soaking nappies are commonly household buckets/bins used for other purposes. It has been decided to omit the manufacture of these bins, as their contribution is considered insignificant, particularly if they may be used for other functions.

Figure 3.2 Outline system diagram for home laundered reusable nappy system`

3.2.4 Commercially laundered nappy system

Laundering services for nappies operate throughout the UK and use prefold or shaped cotton nappies. The Environment Agency surveys (Environment Agency, 2004) identified prefold nappies as dominant amongst commercial laundry users. A week's supply of nappies is delivered to the door, and at the same time the previous week's soiled nappies are collected and delivered to a laundry. Wraps/pants are cleaned in the home.

Prefold nappies are made from cotton in a similar way to terry nappies, see *Section* 3.2.3. Nappies are hired to customers. Service providers also retail liners and wraps to customers. *Figure 3.3* details the main life cycle stages that have been included in the life cycle of commercially laundered reusable nappies.

Figure 3.3 Outline system diagram for commercially laundered reusable nappy system

3.3 Allocation

Some processes may yield more than one product and they may also recycle intermediate products or raw materials. When this occurs, the LCA study has to allocate material and energy flows, as well as environmental releases, to the different products in a logical and reasonable manner.

Where the need for allocation presents itself, then the inputs and outputs of the interrelated product systems have been apportioned in a manner that reflects the underlying physical relationships between them. However, there are certain circumstances where this is not appropriate or possible to do. In the study, an allocation has been conducted for retail energy use using an economic approach. Allocation methods have been documented in the inventory analysis.

3.4 Inclusions/exclusions

3.4.1 Capital equipment

All equipment necessary for any process involved in the life cycle of disposable or reusable nappies is referred to as capital equipment. Examples of capital equipment are:

- washing machines;
- harvesting/forestry machines;
- factory buildings;
- process equipment, e.g. boilers, fans, pumps, pipes etc.; and
- vehicles.

To satisfy the general belief that the production of capital equipment is likely to be insignificant, some previous life cycle studies were consulted. The findings were as follows.

- In 1992, the PA Consulting Group showed, in a life cycle assessment study on washing machines, that the energy consumption of a washing machine is approximately 23 times higher during the use phase compared to the production phase (PA Consulting Group, 1992).
- A life cycle assessment on forestry harvesting machines in 2001 showed that the fossil energy consumption, and hence the global warming potential, associated with the production phase constituted approximately 2-3 per cent of the consumption during the whole life cycle (Cranab AB, 2001).
- In the LCAs performed by Volvo Trucks, the use phase of a truck contributes more than 90 per cent of the environmental burden of the whole life cycle (Volvo Trucks, 2001).

Based on the conclusions of these studies, it was decided to exclude environmental burdens associated with the production of capital equipment.

3.4.2 Workforce burdens

It is not common practice when conducting LCAs to include an assessment of human labour burdens, due to difficulties in allocation, drawing boundaries, obtaining data and differentiating between labour and capital equipment.

For product LCAs where products and production processes are similar, it is reasonable to assume that human labour is the same for each product system, in which case it is reasonable to exclude human labour from the study. This assumption needs to be tested as product systems diverge.

We have excluded human labour as being outside the scope and resources of this project.

3.4.3 Excreta

As discussed in *Section 3.1* on the functional unit, excreta must be considered within the system boundaries when comparing disposable and reusable nappy systems. The main reason for this is that both nappies and the excreta undergo completely different types of waste treatment due to the different characteristics of the systems.

Since many users of disposable nappies have chosen the products, at least partly, for convenience reasons, we believe it is reasonable to assume that all excreta will be disposed together with the nappies. Consequently, excreta will follow the household waste stream all the way from the nappy waste bin in the home to landfill and incineration facilities.

For users of commercial laundered and home laundered reusable nappies, a proportion of the excreta will be flushed down the toilet, together with soiled disposable liners, before the nappies are washed. This effluent will enter the sewerage system. The remaining excreta will enter the sewerage system through the washing machine outflow or from rinsing and soaking. Sewage treatment has been modelled on the basis of typical sewage treatment processes in the UK.

3.5 Key assumptions and limitations

All assumptions have been recorded and reported in this report. All key assumptions have been tested through sensitivity analysis, see *Section 9*. Through a review of previous studies, it has been ascertained that the number of nappy changes and consumer use characteristics are critical to the results.

3.6 Initial data requirements

In addition to collecting data describing the use and manufacture of the nappy types to be assessed, the following were identified as key elements for which inventory data are required:

• UK electricity generation (2001-2002) by type (e.g. coal, gas, nuclear, hydro, wind etc.);

- cotton growing and fabric production;
- detergent manufacture;
- water treatment;
- sewage treatment;
- waste management;
- nappy materials manufacture;
- reusable use scenarios; and
- other commodity material inputs to the systems.

3.6.1 Data quality requirements

The key requirements regarding data quality were that they were representative of nappies used in the UK in 2001-2002.

Data were collected mainly from the following sources:

- questionnaires and interviews with experts regarding the main life cycle stages;
- validated life cycle inventory databases for commodity material and energy inputs to the stages; and
- published literature describing the inputs and outputs from life cycle stages.

The data collected and used for this study have been documented and reviewed with regard to quality by ERM and the peer reviewer.

3.6.2 User surveys

Due to the lack of information regarding the use of nappies on children, the Environment Agency commissioned some questions in the National Statistics Omnibus Survey (June 2002 – February 2003) in relation to the use of reusable and disposable nappies (by children). The survey addressed the types of nappies being used, the average number of changes per day and the age at which children stop using nappies.

Insufficient users of reusable nappies were found in the Omnibus survey, so a second survey targeted at reusable nappy users was commissioned. TEST Research conducted face to face interviews (March - April 2003) with 183 parents.

The purpose of this survey was to establish the types of reusable nappies being used, how they were being used and what other products were being used in support of the nappies, i.e. wraps, booster pads, liners, detergents etc.

The survey findings have been published by the Environment Agency (Environment Agency, 2004).

3.6.3 Data for disposables

The manufacturers of disposables have supplied data describing the average composition and weight of a disposable nappy in 2001-2002, and the average manufacture of disposable nappies. In addition to this, the average weight of packaging by material type that is associated with an average nappy has also been provided.

ERM has been provided with access to the EDANA (European Disposables and Nonwovens Association) life cycle inventories for material inputs to the manufacturing processes. The EDANA database has been developed by IFEU (Institute for Energy and Environmental Research). IFEU are an internationally respected organisation in the field of LCA, and are involved in the development of LCA methodology, conducting LCAs and peer reviews of LCA studies. IFEU were commissioned by EDANA to generate life cycle inventories for all materials associated with the manufacture of disposable nappies. The inventories have been generated by collating data from the producers of nappy manufacturing materials.

The *WISARD* software (Ecobalance, 1999) and supporting literature has been used to model the disposal of disposable nappies.

3.6.4 Data for the home laundered reusable nappy system

The surveys conducted by ERM and the Environment Agency (Environment Agency, 2004) were used to define typical nappy systems. For the specified nappy types, ERM has undertaken a survey to specify the average composition and weight of a nappy and the associated wraps/pants.

To assist ERM in defining the manufacturing process for the reusable nappy system, a survey of nappy manufactures was undertaken. ERM provided questionnaires to over thirty manufacturers, and received, in return, only one complete response.

The ERM sales survey determined that the majority of reusable nappies are purchased from high street shops.

From the Environment Agency surveys, a profile of how nappies are used was generated.

ERM obtained UK data regarding sewage treatment, waste management, washing machine and tumble drier performance.

3.6.5 Commercially laundered nappy system

To assess commercially laundered nappies, we surveyed 22 laundry service providers. Four provided us with usable data regarding collection vehicles, collection distances, nappy usage and laundering activities.

3.6.6 Temporal, spatial and technological scope

The geographical coverage is defined as the use of nappies in the UK in 2001-2002. However, raw material production and some processing occurs outside of the UK. The technologies to be assessed will be representative of the product systems assessed. However, an indication of the age and classification of the technologies has been included in the study.

The geographic, temporal and technological scope of the data has been recorded.

3.7 Inventory analysis

Inventory analysis involves data collection and calculation procedures to quantify relevant inputs and outputs of a product system. For each of the nappy systems assessed, inventories of significant environmental flows to and from the environment, and internal material and energy flows, have been produced. Significance was determined by threshold (more than 1 per cent of inputs) and environmental significance (potential for harm). This has been achieved through the collection of data specific to the processes of each product system.

Data sources include both specific and representative data. It was the ambition of the LCA practitioners to collect specific data relating to the life cycle stages. However, proprietary life cycle databases have been used for common processes, materials, transport steps and electricity generation. Where data are missing, estimates based on literature and previous studies have been made.

The inventories that have been generated provide data on hundreds of internal and elemental flows for each nappy system. Summary inventory for the three systems have been provided in *Annex A*. However, based on a review of previous studies and the views of the advisory board, the following flows have been analysed in detail, for each nappy system:

- water use;
- fossil fuel use;
- solid waste (internal flow);
- COD;
- BOD;
- non-renewable CO₂ emissions;
- CH₄ emissions;
- NO
- NO_x as NO₂; and
- SO₂ emissions.

Water use has been reported in terms of total water use and water used by the main life cycle stages.

In addition, internal waste flows have been reported in terms of total solid waste generation and solid waste generation from the main life cycle stages.

Energy consumption of the main life cycle stages has also been reported, in terms of the electricity and fuel consumed in the manufacturing and use of nappies. However, more detailed analysis of energy consumption has not been assessed as energy is generally an intermediate flow, the interaction with the environment is due to resource consumption (e.g. coal use) and combustion products (e.g. CO₂).

3.8 Impact assessment

The impact assessment phase of an LCA assigns the results of the inventory analysis to different impact categories. The following steps are mandatory:

- selection of impact categories and characterisation models;
- classification, the assignment of LCI results; and
- characterisation, the calculation of inventory burdens potential contribution to impacts.

Selection of appropriate impact categories is an important step in an LCA. We assessed the contribution of each system to the following impact indicators, which we believe address the breadth of environmental issues and for which thorough methodologies have been developed. The study employed the problem oriented approach for the impact assessment, which focuses on:

- global warming;
- ozone depletion;
- photo-oxidant formation;
- depletion of abiotic resources;
- eutrophication;
- acidification;
- human toxicity; and
- aquatic and terrestrial toxicity measures ⁽⁴⁾.

For some impact categories, particularly human toxicity and aquatic and terrestrial eco-toxicity, a number of simplifying assumptions are made in the modelling used to derive characterisation factors. As a result, their adequacy in representing impacts is still the subject of some scientific discussion. However they are still widely used, and we have therefore included them in the assessment as issues of interest, accompanied by caveats describing their deficiencies. The impact assessment reflects potential, not actual, impacts and it takes no account of the local receiving environment.

⁽⁴⁾ See Annex B for further description of these impact categories.

The methodology that we used is that developed and advocated by CML (Centre for Environmental Science, Leiden University) and which is incorporated into the SimaPro ⁽⁵⁾ LCA software tool. The version contained in the software is based on the CML spreadsheet version 2.02 (September 2001) as published on the CML web site and which replaced the preliminary version.

The method used for each impact category for classification and characterisation has been described in *Annex B*.

According to ISO 14042 (ISO, 2000), the following steps may be included but are not mandatory:

- normalisation;
- grouping;
- weighting; and
- data quality analysis.

Whilst some of the category indicator results have been normalised and data quality analysis undertaken, grouping and weighting of indicator results has not be undertaken as part of this study. An important part of the purpose of the study is to indicate the advantages and disadvantages of each system examined in respect of each environmental impact identified, and to highlight hotspots in each system. Neither the Environment Agency, nor the consultants, nor the Advisory Board has any remit to rank the impact categories in order of importance; so weightings have not been applied. Most benefit is obtained by focusing on the quantitative output from LCAs. Therefore, for all three systems, the impacts have been presented separately and an in-depth analysis of each has been made.

3.9 Sensitivity analysis

Key variables and assumptions have been tested to determine their influence on the results of the inventory analysis and impact assessment.

Key areas that have been identified for sensitivity analysis include number of changes and several consumer care characteristics. Due to the permutations associated with reusable nappy systems, sensitivity analysis has formed a significant proportion of the work for this study.

Conclusions made in the study draw on both the primary results for the systems assessed and the variations that result through the sensitivity analysis.

⁽⁵⁾ PRé Consultants bv · Plotterweg 12 · 3821 BB Amersfoort · The Netherlands

3.10 Peer review

In accordance with ISO14040, the study has been peer reviewed by an external reviewer. This reviewer's report is included in the final report and details ERM's responses to the review (see *Annex C*)

The reviewer has addressed the issues below:

- for the goal. and scope:
- ensure that the scope of the study is consistent with the goal of the study, and that both are consistent with ISO 14041; and
- prepare a review statement on the goal and scope.
- for the inventory:
- review the inventory for transparency and consistency with the goal and scope and with ISO14041;
- check data validation and that the data used are consistent with the system boundaries. It is unreasonable to expect the reviewer to check data and calculations beyond a small sample; and
- prepare a review statement.
- for the impact assessment.
- review the impact assessment for appropriateness and conformity to ISO14042; and
- prepare a review statement.
- for the interpretation:
- review the conclusions of the study for appropriateness and conformity with the goal and scope of the study; and
- prepare a review statement.
- for the draft final. report.
- review the draft final report for consistency with reporting guidelines in ISO 14040 and check that recommendations made in previous review statements have been addressed adequately; and
- prepare a review statement including consistency of the study and international standards, scientific and technical validity, transparency and relation between interpretation, limitations and goal.

4 Inventory analysis: disposable nappy system modelling

The disposable systems modelled reflect the average child's use of disposable nappies during the first 2.5 years. This child therefore represents children who stop wearing nappies earlier than 2.5 years, see *Section 3.1*.

This chapter describes both the disposable nappy life cycle system assessed, and the process data and the inventories used to generate a complete life cycle inventory for the system assessed, this information is summarised in *Table 4.5*.

The UK sales figure for disposable nappies in 2001-2002 provided an average daily use figure of 4.16 nappies a day, based on a market penetration of 96.4 per cent (Environment Agency, 2004). The Environment Agency surveys (Environment Agency, 2004) suggested a change frequency, for disposable nappy users, between 4.05 and 4.4 per day over 2.5 years. Due to the clarity of the survey questions and responses, the Agency statistician deemed a daily change of 4.16 to be appropriate and one that is supported by the surveys. An average daily change figure of 4.16 has therefore been used in the assessment of the disposable nappy system.

To determine the quantities and type of materials used to manufacture the disposable nappies, the three largest manufacturers of disposable nappies were provided with questionnaires. The questionnaires also addressed all other production process consumption data (energy, water and materials) and emissions data. The results were then weighted by market share (units) to generate a hypothetical 'average' manufacturing plant.

4.1 Disposable nappy manufacturing

Table 4.1 details the inputs and outputs for the average disposable manufacturing plant. *Table 4.2* details how production waste from manufacturing is managed.

A transport distance allocation of 1000 km of transport by sea and 1000 km of road transport has been assumed for all materials. This assumption is based on the fact that materials are sourced predominantly from the UK and Europe. Based on previous studies, ERM believes that transport is likely to make an insignificant contribution to the overall environmental impacts of the systems studied.

Disposable nappies are manufactured using a continuous mechanical process. The process is fully automated, with nappy components fed into the process and finished packaged nappies produced at the end.

 Table 4.2
 Manufacturing waste management per tonne of nappies produced

4.1.1 Water inventory

Based on data published by Water UK (Water UK, 2003), we have allocated 0.601 kWh per m³ of water supplied. We have assumed that the energy used is electricity. For every m³ of water supplied, 0.12 kg of sludge is generated.

Based on data provided by Water UK (Water UK, 2003), we have allocated 0.598 kWh per m³ of sewage treated. For every m³ of sewage treated, 0.5 kg of dry sludge is produced. This equates to 12.3 kg of wet sludge per m³ of sewage. Based on published research for the UK (Huijbregts *et al.* 2002) we have allocated emissions of 0.0129 kg of methane per m³ of sewage treated. We have also allocated 0.025 kg BOD and 0.125 kg COD and 0.03 kg suspended solids per m³ of sewage treated (ERM estimate based on typical industry data).

4.1.2 Electricity generation

For all three nappy systems, electricity supply and generation models have been created using fuel mix and supply efficiency data for the UK in 2001 (DTI, 2003). For industrial facilities, we have assumed medium voltage supply. BUWAL 250 ⁽⁶⁾ life cycle inventories for energy generation system inventories have been used in the modelling.

⁽⁶⁾ Environmental Series No. 250/1, Swiss Agency for the Environment, Forests and Landscape (SAEFL) Berne, 1998

4.2 Transport to retail outlets

In the absence of logistics data, because the effort required to collect this was not justified on the basis of its assumed significance, it has been assumed that nappies are transported 500 km to retail outlets in 40 tonne trucks.

4.3 Retail outlet

No data has been collected regarding the energy consumption associated with stores retailing nappies. However, a figure was estimated on the basis of energy use in supermarket stores. A typical supermarket store consumed 3.2 million kWh of electricity in 1998, of which refrigeration accounted for 48 per cent and the bakery 8 per cent (J Sainsbury, 1988). If we allocate the remaining 44 per cent on a sales basis, using an average of £29 million sales per store, this equates to 0.049 kWh per pound sterling or 138 kWh per tonne of nappies, assuming 12.7 pence (WEN, 2004) per nappy.

There are a number of alternative allocation methods that might be considered appropriate for this life cycle stage, such as shelf space. No one method stands apart as being correct and the method chosen is considered reasonable. Other methods would require significant resources to gather the required data to no real advantage.

4.4 Transport home

76 per cent of supermarket customers drive to the supermarket. The majority of shoppers, 65 per cent, travel up to ten minutes and the average 'shop' costs £44.31 (Competition Commission, 2000). If we assume this journey is travelled at a speed of 30 mph, this equates to a journey of five miles each way. Assuming a use figure of 4.16 nappies per day and 12.7 pence per nappy (WEN, 2004), this would equate to an 8.3 per cent allocation of the calculated road transport distance per 'shop' based on cost. Assuming a once weekly shop, over the 2.5 years the child is in nappies the car travel allocated to the purchasing of nappies equates to 108.5 miles (174.6 km).

4.5 Use

Based on an average use figure of 4.16 nappies per day, 3796 nappies would be consumed in the first 2.5 years of a child's life. This usage rate equates to 169.5 kg of nappies to be purchased.

For the disposal of urine and faeces to landfill and incineration we have assessed two scenarios, using *Geigy* (Lenter, 1981) and *Forfar* (Campbell and McIntosh, 1998) data; see *Section 1.3.1.* As there is no definitive data set Geigy data has been used for faeces release in both scenarios. The scenarios were as follows:

• **Geigy Scenario:** using the *Geigy* (Lenter, 1981) urine and faeces data (for both volume and composition), and assuming all excreta generated over the 2.5 year period is captured in the nappies (i.e. no potty training). The use of 3796 nappies

would result in 391.4 kg of nappy waste and 3.0 kg (this is only 'use' packaging and does not include retail packaging) of packaging waste.

• **Mixed Scenario:** using the *Forfar* (Campbell and McIntosh, 1998) urine data (for urine volume and composition) and *Geigy* (Lenter, 1981) faeces data (for faeces weight and composition), and assuming all excreta generated over the 2.5 year period is captured in the nappies (i.e. no potty training). The use of 3796 nappies would result in 537.6 kg of nappy waste and 3.0 kg of nappy packaging waste.

4.6 Disposal

In the UK in 2000, approximately 8 per cent of municipal solid waste was incinerated and 80 per cent landfilled. The remainder was recycled or composted, neither of which are currently suitable for managing used disposable nappies in the UK. We have therefore assumed that 9 per cent of the waste generated in the use phase is incinerated and 91 per cent is landfilled. We have used the *WISARD* ⁽⁷⁾ (Ecobalance, 1999) life cycle assessment software tool to generate inventories for the disposal of nappies.

The *WISARD* software tool requires the specification of waste on the basis of the components of municipal waste (see *Annex D* for details of *WISARD*). We have therefore designated excreta as being putrescible waste, fluff pulp as being paper waste and the remainder as plastic waste. *Table 4.4* shows the waste breakdown. *WISARD* quantifies the environmental flows that arise from waste management processes. These will include, inter alia, methane, leachate and combustion products.

The landfill and incinerator inventories for MSW in *WISARD* recover energy through gas management and energy recovery from combustion products. The landfill model assumes 23 per cent fugitive emission of landfill gas and 77 per cent combustion (41 per cent flare and 36 per cent energy recovery) of landfill gas over its life. The incinerator model in *WISARD* assumes that 450 kWh of electricity are generated per tonne of waste. The allocation of excreta as putrescible waste will overestimate the scale of environmental burden, as excreta is has a water content of 86 per cent and putrescible waste in *WISARD* has a moisture content of 62 per cent.

The data presented in *Table 4.3* represent the proportion of children by age that are wearing nappies, based on the user surveys (Environment Agency, 2004). *Table 4.4* shows the quantity of excreta (designated as putrescible fraction) that is contained within nappies for the average child wearing disposables. Excreta generated by children younger than 2.5 years, but who are out of nappies, has been excluded from the study (this has been assumed for all systems assessed).

⁽⁷⁾ Waste: Integrated Systems Assessment for Recovery and Disposal

Age of child	Children wearing nappies (%)	Children not wearing nappies (%)
up to 6 months	100.0%	0.0%
6 to 12 months	95.7%	4.3%
12 to 18 months	82.8%	17.2%
18 to 24 months	45.6%	54.4%
24 to 30 months	17.6%	82.4%
30 to 36 months	4.8%	95.2%
36 to 42 months	1.8%	98.2%

5 Inventory analysis: home laundered reusable nappy system modelling

This section describes the home laundered reusable nappy life cycle system assessed, together with the process data and the inventories used to generate a complete life cycle inventory for the system assessed. This information is summarised in *Table 5.9*.

Due to the diverse nature of reusable nappies and their use, it was necessary to conduct a number of surveys. The surveys were conducted to determine the types of nappies that are being used as well as how they are being used. The surveys were a sales survey conducted by ERM and user surveys commissioned by the Environment Agency (Environment Agency, 2004). The surveys have been used by ERM to define an average reusable nappy scenario. This scenario is tested in the sensitivity analysis based on the variation found in the surveys. This approach has been decided on due to the diverse nature of nappy use and the differences in the surveys.

5.1 ERM sales survey

ERM conducted a survey of nappy retailers and manufactures that determine the sales of the different nappy types in 2000-2001. The survey was not a complete picture of UK sales as not all companies responded. Terry nappies were most popular and accounted for approximately 37 per cent of (direct to user) nappy sales, with prefold nappies at 25 per cent of sales. Direct to user sales totalled 750,000 nappies. Wrap/pant sales to users amounted to 200,000 wraps/pants, over 60 per cent of which were plastic waterproof pants, which are either manufactured from PVC (polyvinyl chloride) or EVA (ethylene vinyl acetate). This survey suggested that for every 10 nappies purchased, 4.0 wraps/pants are purchased.

5.2 Environment Agency's user surveys

TEST Research (part of the MORI Group of research companies) was commissioned by the Environment Agency to undertake a survey of reusable nappy users.

This survey was conducted amongst parents or guardians of children under the age of 36 months who currently use or have used washable cloth nappies. The purpose of this study was to contribute to the Environment Agency's ability to establish the usage of washable cloth nappies and other related nappy products.

• In total, 183 parents/guardians were interviewed face to face in locations within randomly selected constituencies across Britain. Of the 183 respondents, 135 had a child under the age of 36 months and were using washable cloth nappies, eight of which were using a laundry service. The remaining 48 had used cloth

nappies on their child in the recent past. The fieldwork was conducted between 10 March 2003 and 4 April 2003.

A summary of the findings of this and other surveys conducted on behalf of the Environment Agency have been published as a separate report (Environment Agency, 2004).

5.3 Baseline system

Based on the research from the sales survey and the Environment Agency surveys, the following assumptions have been established for the average terry system, shown in *Table 5.1*.

The data presented in *Table 5.1* reflect how consumers use reusable nappies. The systems modelled reflect a decreasing nappy wearing population with time, as with disposable nappies. The data presented in *Table 4.3* show the proportion of children by age that are wearing nappies, based on the Environment Agency surveys (Environment Agency, 2004).

Table 5.2 details the nappy washing assumptions. The data were taken directly from the Environment Agency surveys (Environment Agency, 2004). We have assumed that nappies are washed every two days. This assumption is based on the survey results for the number of people who soak nappies, the number of nappies owned, daily number of changes and that, on average, the survey found that 12 cloth nappies make up a load.

Description	Quantity	Unit	Comment	Source/basis

Table 5.1Reusable terry nappy system assumptions

Description	Quantity	Unit	Comment	Source/basis
Liner type	Disposable liners		86% of users consume one per nappy change. Of users, 50% flushed and 50% disposed to household bin.	ERM assumptions based on the survey data (EA, 2004)
Flushing	2.94	Average daily number.	Corresponds to 86% liner use and a 50:50 split between flushable and non flushable liner use	ERM assumption
Number of bowel movements	2.3	Per day.	57% of faeces flushed to sewer and 43% disposed to household bin.	ERM assumption based on non- flushable liner use amongst Terry users
Soaking	80.0%	Of all users in nappies soak.	Sanitiser used for all soaking and occurs every two days.	EA, 2004
Nappy washing	100%	Of all users machine wash.	Washing occurs every two days.	EA, 2004
Softener	49%	Of users in nappies use softener.	Dosage based on product packaging recommendation.	EA, 2004 and ERM estimate.
Wrap/pant type	18.1	Number used over 2.5 years.	Calculated assuming 15 month life. Plastic waterproof wraps/pants	EA, 2004 and ERM estimate based on longevity question.
Booster pads	4.7	Boosters owned over 2.5 years.	Boosters used 26% of the time.	EA, 2004
Purchasing	0.049	kWh of retail electricity consumed per £ spent.	Assumed that nappies and other nappy materials (liner, detergents, wraps/pants, etc) are purchased in a supermarket.	ERM assumption, sales survey and J Sainsbury, 1988
Nappy washing behaviour	See <i>Table</i> 5.2 detail of washing behaviour.	-	-	EA, 2004
Wrap/pant washing behaviour	6.1	Wraps washed every 2 nd use for children still in nappies.	Assumed wraps are machine washed (mixed load) at 40° C and air dried.	EA, 2004

Description	Quantity	Unit	Comment	Source/basis
Drying behaviour	19%	% of nappy washes tumble dried. Remainder are air dried.	Due to lack of clarity in the data, we have assumed this figure.	EA, 2004
Ironing	9.5%	% of all users in nappies that iron.	Assumed 12 nappies take 5 minutes to iron.	EA, 2004
End of life	Nappies are kept for reuse & wraps are disposed as MSW.	-	Assumed nappies are kept for reuse and wraps/pants are disposed of in domestic waste	ERM assumption, sales survey and J Sainsbury, 1988

* Plastic wraps assumed as it is these that would be worn with a terry nappy.

Table 5.2	Nappy washing
-----------	---------------

Description	Quantity	Unit
Percentage of nappies machine washed	100	%
Percentage of nappies hand washed	0.0	%
Percentage of mixed machine loads	21.0	%
Percentage of separate machine loads	79.0	%
Percentage wash 90°C – nappy	32.1	%
Percentage wash 80°C – nappy	0.0	%
Percentage wash 70°C – nappy	7.1	%
Percentage wash 60°C – nappy	35.7	%
Percentage wash 50°C – nappy	7.1	%
Percentage wash 40°C – nappy	17.9	%

We have assumed that the plastic wraps/pants are machine washed at 40°C and air dried. The survey results related to all types of wraps, some of which are suitable to machine washing. However, we have assumed that all plastic wraps/pants are machine washed and changed every other nappy change.

5.4 Electricity generation

For all three nappy systems, electricity supply and generation models have been created using fuel mix and supply efficiency data for the UK in 2001 (DTI, 2003). For industrial facilities, we have assumed medium voltage supply, for domestic use we have assumed low voltage supply. BUWAL 250 energy generation system inventories have been used in the modelling.

For US electricity input to cotton processing, we have used US specific inventory data published by Franklin Associates, and contained in the SimaPro LCA software.

5.5 Cotton production

Data describing the inputs and outputs associated with the growing and ginning of cotton in the United States has been sourced to enable a life cycle inventory for the production of nappies to be developed. Data specific to the United States has been used due to their availability, quality and the percentage of the world market share that it describes (22 per cent in 2001). Cotton growing regimes are likely to be different in other areas of the world. However, no account of world wide variability has been taken due to the availability of data. The data are shown in *Table 5.3*. No solid waste production has been accounted for as it is considered insignificant.

The following are the main documents from which data was extracted.

- Characteristics and Production Costs of US Cotton Farms, Nora L. Brooks, 2001. USDA.
- USDA Agricultural Chemical Usage 1996 Field Crops Summary.
- 1997 Census of Agriculture; AC97-SP-1USDA. Farm and Ranch Irrigation Survey (1998), Volume 3, Special Studies Part 1.
- Cost of Ginning Cotton. Proceedings of the Beltwide Cotton Conference Volume 1:419-429 (1999).
- National Agricultural Statistics Service, Agricultural Statistics Board, USDA. Crop Production - Annual Summary (Released January 9, 1998).

Input	Quantity	Unit
Insecticides ¹	0.001801	kg

5.6 Cotton yarn production

For yarn spinning, we have allocated material loss and electricity consumption to this stage in the life cycle. Based on work by BTTG (BTTG, 1999) and Rudramoothy *et al.*, (2000), we have allocated 10 kWh per kg of yarn produced and 10 per cent material loss. We have assumed that spinning occurs in the United States. The management of wasted material has been excluded, as it is normal to send this material for recovery/recycling (trash, short fibres and scrap yarn).

5.7 Transport of yarn to the UK

We have allocated 6500 km of sea transport (New York to UK) and 1000 km of road transport (transport in UK and US).

5.8 Nappy and booster manufacture

Manufacturers of terry nappies were contacted and requested to fill in a questionnaire describing the production process. Disappointingly, only one company completed the questionnaire, despite numerous requests by ERM. Therefore, the data described in *Table 5.4* cannot be considered representative of all terry nappies. However, the data set is considered to be of good quality. Furthermore nappy manufacture and cotton production are not the most significant elements of the life cycle (considering the consumption of energy in the use phase and that 47.5 terry nappies would weigh approximately 5.46 kg).

Some terry nappies are produced in the UK, but the majority are believed to be produced in the Far East, India and Pakistan.

The Environment Agency surveys showed an average ownership of 4.7 boosters per child, weighing approximately 0.21 kg, and that boosters are used 26% of the time. Due to the low mass of boosters relative to nappies their manufacture has been excluded.

Input	Quantity	kg
Hydrogen peroxide (35%)	71	kg
Formic acid	5	kg
Caustic soda (50%)	18	litres
Optical whitener	18	litres
Softener	30	litres
Water	18,000	litres
Grid electricity	1792	kWh
Natural gas	11,246	kWh

 Table 5.4
 Terry nappy manufacturing inputs per tonne of nappies produced

Source: UK terry nappy manufacturer

A survey of terry nappies by ERM found that for every 1 kg of nappies there is an associated 12 g of PE packaging. Terry nappies were found to weigh between 100 g and 130 g. We have used 115 g as an average.

5.9 Wrap/pant manufacture

No specific data were collected regarding wrap/pant production, due to the small quantity of material involved. Plastic wraps/pants were found to range between 14 g and 20 g in weight. We have used 17 g per wrap/pant.

A survey of plastic waterproof wraps/pants by ERM identified two main construction materials. These are EVA (ethylene vinyl acetate) and PVC (polyvinyl chloride).

The average child uses 18.1 wraps/pants. This equates to 0.308 kg of wraps/pants. This is a small quantity of material and has therefore been excluded from the analysis.

5.10 Liner manufacture

No specific data were collected regarding disposable liner production. Based on the Environment Agency survey ERM have assumed 100 per cent disposable liners, 50 per cent flushable and 50 per cent non flushable. Of the terry users who use liners, 94 per cent use disposable liners and of these 53 per cent use flushable and 47 per cent use non-flushable. ERM research identified two main types of liner, non woven polypropylene based and cellulose based liners. We have used generic life cycle data for the production of polypropylene and paper to represent liner manufacture. The average weight of a liner was found to be 1.4 g. Polyethylene packaging associated with the liners amounts to 5.4 g per 100 liners.

5.11 Detergent manufacture

Based on the breakdown of detergent usage in the Environment Agency surveys, ERM has been provided with a weighted average (weighted by type of detergent (Environment Agency, 2004) and recommended dosage) life cycle inventory for detergent use per wash. The inventory includes manufacture of detergent and packaging, transport and post treatment of washing machine effluent. Treatment of effluent from washing machines has therefore been excluded from the inventories generated by ERM. The average dose that this corresponds to is 108 g. This data has been published and peer reviewed (Van Hoof *et al.* 2001, 2003a,b). The average dose that this corresponds to is 108 g. This data has been published to is 108 g. This is consistent with data presented by GEA (GEA, 1995). Their report addressed average consumer behaviour (1994), reporting an average load of 3 kg per wash and an average detergent use of 135 g per wash. The reduction from 135 g to 108 g is consistent with the rise in concentrated detergents. Detergent packaging per wash has been calculated to be 6.6 g. We have assumed that this is cardboard.

5.11.1 Transport to retail outlet

In the absence of logistics data, it has been assumed that nappies and other materials are transported 500 km to retail outlets in 40 tonne trucks, with a utilisation of 75 per cent.

5.12 Retail outlet (detergent, sanitiser, liners, softener)

For the purposes of this study, we have assumed the same electricity consumption per \pounds of sales as used for retail premises in the disposable system, 0.049 kWh/ \pounds .

The unit prices we have used are detailed in *Table 5.5*. These prices are based on an internet search supermarket prices.

There are several allocation methods that are considered appropriate for this life cycle stage, such as shelf space. No one method stands apart as being correct and the method chosen is considered reasonable. The other methods would require significant resources to gather the required data to no real advantage.

Description	Unit	Price per unit, £	No of units	Cost over 2.5 years
Terry nappy*	1 nappy	1.90	47.5	£90.25
Detergent	1 kg	1.30	30.8	£40.03
Sanitiser	1 kg	6.00	10.2	£61.32
Liners	100	2.70	32.7	£88.31
Softener	1 kg	0.89	15.3	£13.59
Wrap/pant*	1 wrap/pant	0.40	19.2	£7.68
Total				£301.18

Table 5.5Purchase price of reusable nappy materials

* Wraps/pants and nappies are a relatively insignificant cost. Therefore we have assumed that they are purchased in a supermarket. In reality, they would be purchased on the high street, via mail order or through the Internet.

5.13 Transport of nappy materials home

As for disposables, 76 per cent of supermarket customers drive to the supermarket. The majority of shoppers, 65 per cent, travel up to ten minutes and the average 'shop' costs £44.31 (Competition Commission, 2000). If we assume this journey is travelled at a speed of 30 mph, this equates to a journey distance of five miles each way. Assuming a shopping value of £301.18, this would equate to a 5.2 per cent allocation of the calculated road transport distance per 'shop' based on cost. Assuming a once weekly shop, over the 2.5 years the child is in nappies this car travel associated with the purchasing of nappies equates to 67.9 miles (109.4 km).

5.14 Nappy use

Children up to 2.5 yrs, who are in nappies, use an average of 6.1 nappies per day, of which 2.3 will contain bowel movements (Environment Agency, 2004). We have assumed that, for every change, 50 per cent of the liners are flushed down the toilet and 50 per cent are disposed of in the household bin (there was an equal split between flushable and non flushable liner use). The Environment Agency surveys showed that 86 per cent of parents use liners in tandem with nappies. Used nappies are soaked in a sanitising solution. Based on the percentage of people soaking, the number of nappies owned and the change frequency we have assumed that nappy washing takes place every two days.

5.14.1 Flushing

According to the National Home Improvement Council, pre 1995 WCs typically consume nine litres per flush. New WCs use a maximum of seven litres per flush.

We have assumed seven litres, this allows for the low flush developments and pre 1995 WCs.

5.14.2 Soaking

We have assumed that 80 per cent of nappies are soaked in a bin and that an average water volume of ten litres is used. For the sanitizer we have assumed that nappy soak is used. The composition of nappy soak is detailed in *Table 5.6*.

Component	% (Recorded on product packaging)	Assumed
Sodium carbonate	15-30	30
Sodium percarbonate	15-30	30
Organic sequestering agent	5-15	15
Anionic surfactant	<5	5
Cellulose colloids	<5	5
Tetraacetylethylenediamine activator	<5	5

Table 5.6Nappy soak composition

5.14.3 Washing

Using data from Defra's Market Transformation Programme (Defra data), we have calculated that each year 8.5 per cent of washing machines are replaced, this suggest a life span of 11.7 years for a washing machine. To reflect actual energy consumption by washing machines in the UK in 2001-2002, it is appropriate to model machine performance of machines sold in 1995-1996. However, due to data limitations, we have used sales data for 1997 to calculate energy consumption, see *Table 5.7*. This is likely to underestimate energy consumption. AISE in their submission to the European Commission (AISE, 2002) quote average electricity consumption figures, for the UK, per wash, of 1.61 kWh at 60°C, and 2.5 kWh at 90°C. The Group for Efficient Appliances in 1995 report, for Europe, 2.06 kWh for 90°C and 1.19 kWh at 60°C.

According to the Environment Agency (8) washing machines use between 50 and 100 litres per wash. We have assumed 75 litres per wash.

For mixed load washing, we have assumed full loads and allocated consumption data on a mass basis. We have assumed a 3.00 kg average load for mixed loads (GEA, 1995).

5.14.4 **Detergent use**

See Section 5.11.

5.14.5 Softener use

Although reusable nappy promoters recommend not to use fabric softener when washing nappies, the Environment Agency's surveys (Environment Agency, 2004) showed that an average of 49% of users in nappies use softener. ERM has determined an average softener dose of 0.1kg per wash, based on product packaging recommendations. The composition of the softener is shown in Table 5.8.

Table 5.8	Fabric softener composition

Eabric cofferer composition Tabla E O

Tumble drier 5.14.6

Cationic surfactants

Water

Due to limitations of the survey, no precise data were gained regarding percentage of washes that are tumble dried. Survey respondents made multiple choices regarding drying. 50 per cent of terry users in the Environment Agency surveys selected the tumble drying option. However, tumble drying selection totalled 19 per cent of all the

5-10%

-

10%

90%

selections made. We have assumed that tumble driers are used to dry 19 per cent of nappy wash loads. This is considered a weak assumption, and expected to be a minimum. Energy use for tumble driers has been estimated to be 0.75 kWh per kg of cotton. This estimate is based on LCA work undertaken by ERM for Marks and Spencer Plc in 2001-2002 (ERM, 2002).

The Office of National Statistics (ONS) found that depending on socio economic classification that ownership of tumble driers in 2002 ranged from 45 to 71 percent of households, ownership of tumble driers in the UK was 54.5 per cent and is increasing with time (ONS, 2002). 58 per cent of lone parent families own tumble driers and 72 per cent of other families own tumble driers. 65 per cent of small families and 74 per cent of large families own tumble driers (ONS, 2002). The ONS survey does not provide data according to age of children.

The group for efficient appliance suggest an average tumble drier activity of 60 per cent compared with washing (GEA, 1995). This a Europe-wide report and does not reflect families alone.

Different levels of tumble drying has been tested in the sensitivity.

5.14.7 Ironing

We have assumed that 9.5 per cent of all users iron their nappies, based on the Environment Agency's surveys (Environment Agency, 2004). Energy consumption from nappy ironing was based on an iron rated at 1.9 kW and an average ironing time of 5 minutes per 12 nappies. This equates to 0.015 kWh of electricity consumption per 12 nappies.

5.14.8 Wrap/pant washing

Based on the Environment Agency's surveys (Environment Agency, 2004) we have assumed that the plastic wraps/pants are washed in a mixed load at 40°C and air dried. Consumption of water, electricity and detergent associated with mixed load wrap/pant washing has been allocated on a mass basis. We have assumed full loads and allocated consumption data on a 3.00 kg average load (GEA, 1995).

5.14.9 Water supply and disposal

For data used to describe water supply and treatment see Section 4.1.1

We have assessed flush and soaking water using the sewage treatment data. Washing machine water consumption and effluent treatment is included in the detergent inventory.

5.15 End of life

We have assumed that nappies are kept for reuse and that wraps/pants are disposed of with domestic waste.

5.16 Life cycle inventories used

Table 5.9 details the life cycle inventories that have been used to describe the input and outputs from the reusable nappy system. These flows are described in *Figure 5.1*, assuming Geigy excreta scenario, and in *Figure 5.2*, assuming the Forfar excreta scenario.

Note: see Section 11.2 for a glossary of life cycle inventory sources.

6 Inventory analysis: reusable commercially laundered nappy system modelling

This section describes the commercially laundered reusable nappy life cycle system that has been assessed, together with the process data and the inventories used to generate a complete life cycle inventory for the system assessed, this information is summarised in *Table 6.8*.

ERM provided UK reusable nappy service providers and nappy manufacturers with questionnaires. The questionnaires were used to determine the quantities and type of materials used in the manufacture and delivery of commercially laundered nappies, also addressed was the process consumption (energy, water and materials) and emissions data. Three laundry service questionnaires were fully completed and one was partially completed. All the data reviewed were used to generate a hypothetical 'average' service provider, weighted by market share (units). The four service providers represented an annual service provision of nearly 1.8 million nappies. One nappy manufacturer completed the manufacturing questionnaire.

A nappy laundry service delivers to the user's home on a weekly basis, the necessary supply of cotton reusable nappies, disposable liners and deodoriser discs. Polyester wraps/pants are supplied on a one-off basis. Soiled nappies, which are stored in a dry deodorised bin in the home, are collected at the same time as the delivery of clean nappies. The laundry service will rinse, wash, and tumble dry soiled nappies before delivery by van to the customer. Users of this service do not need to purchase any further supplies of nappies.

Based on responses from nappy laundries, it has been calculated that the average service provider delivers approximately 37.7 prefold nappies (or 2.85 kg) per child per week for the 2.5 years that the child is in nappies. Based on communication with commercial laundries, we have assumed that the average service provider will stock 52.5 prefold nappies (or 3.96 kg) per child over the 2.5 year period.

As detailed earlier, a number of surveys (Environment Agency, 2004) were commissioned relating to the use of reusable nappies. These surveys have been used by ERM to define some of user activities in the home (wrap washing, flushing etc.).

 Table 6.1
 Commercially laundered reusable nappy assumptions

The commercially laundered inventory analysis reflects the average UK child using a commercial laundry. It therefore takes account of the decreasing nappy wearing population, as with the disposable and reusable systems. The data presented in *Table 4.3* show the proportion of children by age that are wearing nappies, based on consumer surveys (Environment Agency, 2004).

6.1 Electricity generation

For all three nappy systems, electricity supply and generation models have been created using fuel mix and supply efficiency data for the UK in 2001 (DTI, 2003). For industrial facilities, we have assumed medium voltage supply, and for domestic use, we have assumed low voltage supply. BUWAL 250 energy generation system inventories have been used in the modelling.

For the electricity input into prefold manufacture we have used Pakistan energy data for 2001, sourced from the International Energy Agency. We have used BUWAL 250 energy generation system inventories to generate a Pakistan specific inventory in the modelling

6.2 Cotton production

See Section 5.5 for data describing the inputs and outputs associated with cotton growing and ginning.

6.3 Nappy manufacture

Manufacturers of prefold nappies were contacted and requested to fill in a questionnaire describing the production process. There was a disappointing response to the questionnaires, not all companies responded, and only one fully completed questionnaire was received, despite repeated reminders by ERM. As such, the data described in *Table 6.2* that represents cotton spinning, weaving, bleaching and stitching processes, is not considered representative of all prefold nappies. However, the data set is considered to be of good quality and nappy manufacture and cotton production are not the most significant elements of the life cycle (considering the consumption of energy in the use phase and that 52.5 terry nappies would weigh approximately 3.96 kg). The data shown in *Table* 6.2 represent spinning, weaving and stitching to produce one tonne of prefold nappies. The overall production loss for these processes is 12 per cent by weight.

The majority of prefold nappies are thought to be produced in the Far East, India and Pakistan. For the basis of this study, we have assumed Pakistan.

Table 6.2Prefold nappy manufacturing inputs per tonne of prefold nappies
produced

Prefold production	Quantity	Unit	
Cotton lint	1120	kg	
Ground water	42000	kġ	
Electricity	51100.0	kŴh	
Gas	10553.2	kWh	
Hydrogen peroxide	292	kg	

Source: Prefold nappy manufacturer in Pakistan

No data were collected for emissions to air. However, generic life cycle data for the combustion of fuels has been used. Primary data was available for the emissions to water, which is shown in *Table 6.3* and *Table 6.4*. For the emissions to surface water, we have accounted for these as environmental burdens and for emissions to sewer, we have used the inventory for sewage treatment (See Section 4.1.1) amended for electricity generation in Pakistan.

Table 6.4Effluent emissions to sewer

For sewage treatment, equivalent performance to UK sewage treatment has been assumed.

It has been assumed that there is no significant packaging associated with the manufacture of prefold nappies. On analysis of prefold nappies provided to ERM it was found that the average weight of a prefold nappy is 75.5 g.

6.4 Transport of prefold nappies to the UK

We have allocated 11,000 km of sea transport (Pakistan to Southampton via the Suez canal) and 1000 km of road transport.

6.5 Wrap/pant manufacture

No specific data were collected regarding wrap production, due to the small quantity of material involved. It is common to use polyester wraps in combination with prefold nappies. Commercial laundries do not launder wraps but sell wraps to their customers.

A survey of polyester wraps by ERM generated an average weight of 43 g. The average user consumes 6.6 wraps per year that a child is in nappies. This equates to 0.485 kg of wraps. We have used generic life cycle inventory data for the production of polyester fabric.

6.6 Liner manufacture

See section 5.10.

6.7 Commercial detergent use by laundries

Detergent composition and consumption for the 2.5 year period was determined based on the breakdown of detergent usage from the ERM questionnaire supplied to commercial laundry service providers, and through contacting the detergent manufacturers. This is shown in *Table 6.5*. ERM conducted a survey that determined the detergent packaging per 1 kg of detergent to be 0.002 kg PP (polypropylene) and 0.0003 kg PE (polyethylene). ERM has generated a life cycle inventory for the production of detergent primarily based on life cycle inventory data from EMPA (EMPA, 2002).

Item	Ingredient	Quantity (%)	Assumed (%)	Active amount (kg) used in 2.5 years	Total amount (kg) used in 2.5 years
Detergent powder	Sodium carbonate	>30%	30%	1.830	6.10
	Disodium metasilicate	15-30%	30%	1.830	
	Sodium hydroxide	5-15%	15%	0.915	
	Alkyl alcohol alkoxylate	<5%	5%	0.305	
Sodium perborate powder	Sodium perborate tetrahydrate	>98%	98%	2.431	2.48
Sodium hypochlorite	Sodium hypochlorite	10-13%	13%	0.368	2.83
Neutraliser	Disodium disulphite	>30%	30%	0.321	1.07

Table 6.5 Detergent compositions

6.7.1 Transport to laundry service provider

In the absence of logistics data, it has been assumed that nappies and other materials are transported 500 km.

It has been assumed that laundry service providers supply nappies, wraps and liners. Wraps are assumed to be washed in the home, and, only, nappies are collected by the nappy laundry service provider for cleaning.

6.8 Laundry service vehicle use

Prefold nappies and other accessories are delivered on a once weekly basis by van. Based on the ERM survey, the average round trip delivery distance is 3.88 miles per child per week, which equates to a distance of 504.7 miles (ie 812 km) over the 2.5 year period. The associated fuel consumption per average child for the first 2.5 years is shown in *Table 6.6*. The service providers contacted use a mixture of vehicles and fuels.

Table 6.6Nappy laundry service vehicle fuel use per child per 2.5 years

Input	Quantity	Unit
Diesel	21.3	litres
Petrol	0.55	litres
Liquefied propane gas (LPG)	8.0	litres

6.9 Laundry service washing

Based on data from the ERM survey of commercially laundered nappy service providers, the following data were determined (*Table 6.7*) relating to a service provision of 2.5 years period per child. The data presented in *Table* 6.7 represents an average service provider.

Input	Quantity	Unit				
Grid electricity	331.6	kWh				
Natural gas	1093.5	kWh				
Water	16,097	kg				
Detergent powder	6.10	kg				
Sodium perborate powder	2.48	kg				
Sodium hypochlorite	2.83	kg				
Neutraliser	1.07	kg				
Wraps/pants*	0.485	kg				
Liners (disposable, PP) *	2.29	kg				
Liners (disposable, cellulose)*	2.29	kg				
PP packaging	0.036	kg				
PE packaging	0.181	kg				
* Not all laundry service providers supply all the necessary liners and						
wraps used during the 2.5 years a child is in nappies. However, in this						

Table 6.7Inputs to prefold nappy laundry service for the first 2.5 years of an
average child's life

scenario we have assumed that they do.

No data for laundry effluent quality was collected. We have used the inventory for sewage treatment, see *Section 5.14.9*.

6.10 Retail outlet (nappies)

For the purposes of this study, it has been assumed that all nappy materials, except for detergent used for wrap/pant washing, are supplied by the service provider. See *Section 6.11.3* for details of wrap/pant washing.

6.11 Nappy use

For children in nappies, 6.1 nappies on average are used per day, of which 2.3 will contain bowel movements. We have assumed that, for every change, 50% of the liners are flushed down the toilet and 50% are disposed of in the household bin. The consumer surveys (Environment Agency, 2004) showed that liners are used 86% of the time. Used nappies are stored in a dry bin until collection.

6.11.1 Flushing

According to the National Home Improvement Council, pre 1995 WCs typically consume nine litres per flush. New WCs use a maximum of seven litres per flush. We have assumed seven litres per flush. Excreta and liner disposal have been modelled in the same way as for the reusable home use system.

6.11.2 Nappy storage

We have assumed that all used nappies are stored in a dry bin and that deodoriser tablets are not used.

6.11.3 Wrap washing

We have assumed that wraps are washed in a mixed load (ie with other washing) at 40°C.

Using data from Defra's Market Transformation Program (Defra data), we have calculated electricity use per wash by wash temperature for an average washing machine, based on the market penetration of different energy grade washing machines, see *Section 5.14.3*.

According to the Environment Agency washing machines use between 50 and 100 litres per wash. We have assumed 75 litres per wash.

For consumption of water, electricity and detergent associated with mixed load wrap washing, we have assumed full loads and allocated consumption data on a mass basis. We have assumed a 3.00 kg total average load for mixed loads (GEA, 1995).

6.11.4 Home detergent use

See Section 5.11 for details regarding detergent use.

6.11.5 Water supply and disposal

See Section 5.14.9 for details relating to water supply and disposal.

6.12 End of life

We have assumed that nappies are sold by service providers for reuse and that wraps are disposed of with household waste.

6.13 Life cycle inventories used

Table 6.8 details the life cycle inventories that have been used to describe the input and outputs from the commercially laundered nappy system. These flows are presented graphically in *Figure 6.1*, assuming Geigy excreta scenario, and in *Figure 6.2* assuming the Forfar excreta scenario.

Figure 6.1 System diagram for commercially laundered reusable nappies (Geigy Excreta Scenario)

7 Inventory analysis: results for disposable and reusable nappy systems

7.1 Disposable nappies

Summary inventory data for the disposable nappy system, assuming 4.16 changes per day, are detailed in *Table 7.1* and *Table 7.2*. Manufacture of disposable nappy materials and production of disposable nappies result in the majority of the inventory burdens assessed. End of life waste management is the most significant source of methane emissions and, as would be expected, dominates solid wastes disposed (this is an internal flow).

				Life Cycle Stage

86 Life Cycle Assessment of Disposable and Reusable Nappies in the UK

⁽¹⁰⁾ The COD emission for end of life is considered too low and is the result of COD being under reported in *WISARD*.

					Life	Cycle Stage	
Substance	Flow Type	Unit	Total	Consumer transport home	and	Raw materials, transport and nappy manufacture	End of life waste management
		kg	53.7	0	7.6	60.9	-14.7
Crude oil	Resource	%	100	9.8	3.2	86.4	0.6
		kg	107	11	3	93	1
Natural gas	Resource	%	100	0.6	0.6	98.6	0.1
		kg	87.8	0.6	0.5	86.6	0.1
Water	Resource	%	100	0.0	0.4	99.5	0.1
		kg	34362	1	135	34200	27
Solid waste (11)	Waste	%	100	0	1.4	13.5	85.2
		kg	519	0	7	70	442
BOD	Water	%	100	0	0.7	22.3	77.0
		kg	0.797	0	0.006	0.178	0.613
COD (12)	Water	%	100	0	-8	108	0
		kg	1.40	0	-0.11	1.51	0

Note: Negative values in the table relate to the environmental benefit associated with recycling materials and recovering energy.

The differences in the mixed and Geigy scenario inventory tables result from the different quantities of putrescible material sent to landfill and incineration.

Table7.3 is an analysis of the inventory burdens for disposable nappy manufacture. The main sources for the inventory burdens assessed are the production of the main materials of manufacture for disposables and the generation of the electricity used in disposable nappy fabrication.

⁽¹¹⁾ Internal flow that is reported as a point of interest.

⁽¹²⁾ The COD emission for end of life is considered too low and is the result of COD being under reported in *WISARD*.

Table7.3 Inventory analysis - disposable nappy manufacture

(1) Internal flow that is reported as a point of interest.

(2) The COD emission for end of life is considered too low and is the result of COD being under reported in WISARD.

7.2 Reusable nappies home use

Table7.4 details the summary inventory for the reusable nappy system. The main sources for the inventory burdens assessed are the production of detergent and the generation of the electricity used in nappy washing. Terry nappy manufacture is a generally small contributor to the life cycle inventory burdens assessed, with the exception of water use; cotton growing being a major user of unprocessed water.

7.3 Commercial laundry

Table details the summary inventory for the commercial laundry nappy system. The main sources for the inventory burdens assessed are the production and use of electricity and gas by laundries, the transport of nappies to and from the home. Prefold nappy manufacture is a surprisingly high contributor to the life cycle inventory burdens assessed. By comparison with home use, more nappies are used over the 2.5 years, which would account for some of the increase in the contribution from nappy manufacture. The data for prefold nappy manufacture suggests it is also more energy intensive than terry nappy manufacture.

									Life C	ycle Stage

Fresh water aquatic ecotox.	kg 1,4-DB eq	7.01	5.98
Terrestrial. ecotoxicity	kg 1,4-DB eq	1.92	1.9

Table 8.1Impact profile for disposable nappy systems (1 child 2.5 years 4.16
Changes per Day)

Note: italics indicate less well developed impact methodologies

8.1.1 Analysis of the mixed scenario

Table 8.2 details the contributions to the impact assessment for the mixed disposable nappy scenario, assuming 4.16 changes per day. As can be seen from the most significant elements of the life cycle are upstream of nappy retail (including material production), with the exception of ozone depletion and aquatic toxicity impacts, end of life waste management being a significant contributor. Transport home by consumers contributes a surprising amount of the impact burdens. Disposable nappy manufacture is further analysed in *Table 8.12*.

Impact Category	Unit	Total	Raw materials, nappy manufacture and transport to retail	Retail electricity and packaging	Consumer transport home	End of life waste management

8.1.2 Disposable nappy manufacturing

Table 8.12 shows the contribution from each element of the life cycle upstream of retail to the impacts associated with their total contribution. The production of super absorbent polymer is the largest source of environmental impact burdens for these stages of the life cycle. Fluff pulp is not as significant as would be expected considering the quantity of material. To check that the data provided was reasonable, we have conducted a comparison of the fluff pulp inventory from EDANA with the BUWAL inventory for bleached sulphate pulp. This comparison showed the fluff pulp inventory to be have higher impact values for the main environmental impact categories. This is presented in *Figure 8.1*. As the fluff pulp inventory is more up to date and specific to disposable nappies it is considered reasonable.

Figure 8.1 Pulp comparison

8.2 Reusable nappies home laundering

Table 8.13 details the impact assessment for the reusable home laundering nappy systems, for 1 child and 2.5 years. Electricity use for nappy care is the most significant single contributor to the impacts assessed.

Impact Category	Unit	Total	Fluff pulp	SAP	PE film	Adhesive s	Lime ston e	Adhesive tape	PET	PP	Cardboard and plastic packaging	Transport	Electricity	Heat gas	Waste recycling	Waste disposal

Table 8.13 Impact profile - cloth nappy home laundering (Mixed Scenario: 1 child, 2.5 years)

Note: italics indicate less well developed impact methodologies

* The methodology for fresh water aquatic ecotoxicity is not well developed and does not include characterisation factors for many detergent chemicals that are likely to pass through waste water treatment works unchanged. Work conducted by Procter and Gamble and CML (Jeroen Guinee and Arjan de Koning) suggest that the toxicity loading that would arise per wash would amount to 1.49 kg 1,4-dichlorobenzene eq (DCBeq). This would result in the aquatic toxicity increasing to more than 400 kg 1,4-dichlorobenzene for the nappy use system. Detergent use would therefore contribute 100% of the life cycle aquatic toxicity impact.

The following nine tables identify which of the individual environmental burdens are responsible for the impact values above.

8.3 Commercial laundry

Table 8.23 details the impact assessment for the commercial laundry nappy systems. Energy use at the laundry is the most significant contributor to the impacts assessed, vehicle use in the delivery and collection of nappies is also a significant contributor. Prefold nappy manufacture is significantly higher than terry nappy manufacture in the home use scenario. Prefold manufacture is analysed in *Table 8.33*.

9 Sensitivity analysis and normalisation

This section describes the sensitivity analysis and normalisation undertaken as part of this study. Sensitivity analysis is a process where key input parameters about which there may be uncertainty or for which a range of values may exist are deliberately varied in the modelling and shows the effect that such variation could have had on the results of the assessment. The sensitivity analyses carried out and reported here were agreed by the project board. Normalisation attempts to compare the impacts from the systems studied to the impacts of some everyday activity or to a proportion of the same impact but from a wider system.

9.1 Number of changes

The user surveys and the sales data for disposables corroborate each other in terms of changes per day. However, due to issues of clarity in the survey we have assessed a lower use figure, 4.05 changes per day. *Figure 9.1* shows the implication of this change.

Figure 9.1 Normalised comparison of 4.05 changes with 4.16 changes

9.2 Omitted materials manufacture

Although small in mass, we have assessed the implication of the assumption to exclude minor inputs. We have done this by including an equivalent amount of super absorbent polymer. *Figure 9.2* shows the implication of this change.

Figure 9.2 Normalised comparison: omitted material sensitivity

9.2.1 Disposal assumptions

A significant assumption in the study is the use of *WISARD* data for the disposal of excreta. We have assumed that the excreta contained in the nappies is putrescible waste, and that the waste management burdens are the same as those for the disposal of putrescible waste. This approach has, in our opinion, overestimated the burden associated with waste disposal, as the majority of the excreta is water. To assess this assumption, we removed putrescible waste management from the system. *Figure 9.3* shows the implications of this change. This change results in a significant reduction (greater than 10 per cent) in the ozone depletion, eutrophication and photochemical smog impacts.

Figure 9.3 Normalised comparison: waste management sensitivity

9.2.2 Chemical oxygen demand

On analysis of the *WISARD* life cycle tool, it is believed that the COD emissions is under reported, as it is impossible for COD emission to be lower than BOD emission. To test the significance of this error, we have assessed a COD emission that is equivalent to the BOD emission from end of life. This change results in a 6 per cent increase in the eutrophication impact, no change occurs to other impacts.

9.3 Sensitivity of the reusable nappies home use system

9.3.1 Tumble drying

There is a significant level of uncertainty as to the use of tumble driers for drying nappies. *Figure 9.4* shows the implication of increasing tumble drying from 19 per cent (baseline) of washes to 60 per cent of washes. This is an ERM estimate based on family tumble drier ownership being between 65 per cent and 74 per cent of families (ONS, 2002). The group for efficient appliance suggest an average tumble drier activity of 60 per cent compared with washing (GEA, 1995). This a Europe-wide report and does not reflect families alone.

Figure 9.4 60% tumble dry

9.3.2 Electricity consumption washing

There is some uncertainty regarding washing machine electricity consumption in 2002. In the baseline model, we assumed performance of a machine sold in 1997, as washing machine life is approximately 12 years. *Figure 9.5* shows the implication of using average wash consumption data for machines sold in 2000.

Figure 9.5 Washing machine electricity consumption

9.3.3 Omitted material manufacture

Due to the low mass of wraps and boosters entering the retail stage, their manufacture was excluded from the study. *Figure 9.6* shows the implication of including these products. For boosters, we used terry manufacture as being analogous to booster manufacture. For wraps/pants, we assumed PVC as this was the most common material for wraps (Environment Agency, 2004).

Figure 9.6 Including boosters and wraps

9.3.4 Liner disposal

There is a high level of uncertainty as to how used liners are disposed. In this study we have assumed that 86 per cent of users consume one liner per nappy change and that 50 per cent are flushed and 50 per cent disposed to household bin. *Figure 9.7* shows the implication of flushing all liners. With the exception of the ozone depletion impact no significant difference (greater than 10 per cent) is observed.

9.3.5 Number of nappies owned, previous use and waste management

It was difficult to determine actual numbers of nappies purchased per child over the 2.5 years from the surveys. The ERM sales survey found that at least 750,000 reusable nappies were sold in 2001-2002. Based on the reusable nappy wearing population, this would suggest a minimum of 30 nappies purchased over the 2.5 years. Using the same calculation method for terry nappies, the minimum purchased is calculated to be 43 nappies over the 2.5 years.

We have used a figure of 47.5 for the terry system in the study, based on minimum ownership in any one six month period. This is considered to be a weak assumption based on the limited number of responses, however it is considered a reasonable assumption based on the sales survey.

We have not allocated any disposal burden for terry nappies to the system, as nappies tend to be reused for other purposes within the home, including use on another child. There is a high level of uncertainty associated with this assumption. However, when considering the mass involved it is not considered significant.

9.3.6 Nappy type

The study reflects home use of the most popular reusable nappies, terry nappies. The environmental impacts associated with other nappy types such as prefold and shaped will be of a similar scale to the terry nappy system assessed. Although ownership patterns are likely to be different, due to cost, engineering and size differentiation.

9.3.7 Aquatic toxicity

The methodology for fresh water aquatic ecotoxicity is not well developed and does not include characterisation factors for many detergent chemicals that are likely to pass through waste water treatment works unchanged. Work conducted by Procter and Gamble and Leiden University (Jeroen Guinee and Arjan de Koning) suggest that the toxicity loading that would arise per wash would amount to 2.19 kg 1,4-dichlorobenzene eq (DCBeq) per laundry wash and 1.49 kg 1,4-dichlorobenzene eq (DCBeq) per home wash. This would increase the aquatic toxicity impact value to over 400 kg 1,4-dichlorobenzene equivalents for the terry nappy system. This is a massive increase in this impact burden. The new characterisation factors that have been developed by CML are to be published later this year.

9.4 Sensitivity of the commercial laundry system

9.4.1 Prefold nappy manufacture (includes raw materials, energy generation and transport to the UK)

Prefold nappy manufacture is a surprising contributor to the impact profile of the commercial laundry system. The majority of the impact contribution is associated with energy consumption, in particular electricity generation. Prefold manufacture from lint to nappy consumes 61,653 kWh of fuel/electricity input per tonne of nappies (82 per cent electricity). Terry nappy production from lint consumes approximately 23,938 kWh of fuel/electricity input per tonne of nappies (53 per cent electricity). This is a significant difference and worthy of note. The lack of data sets for prefold manufacture is a limitation of the study.

They both consume, approximately, the same amount of natural gas, and it is electricity consumption that differs. This would suggest that differences in yarn spinning, knitting/weaving processes might be the source of the difference, since spinning is a significant user of electricity.

For terry nappies we have assumed 10,000 kWh per tonne of yarn produced. This is a representative figure for spinning, although spinning mills vary markedly across the world and with the age of the technology employed. For prefold manufacture, we have used one data source (this includes all operations from lint input to final nappy output), for terry production we have used one data source for production stages post yarn spinning.

There is therefore a significant level of uncertainty with regard to this stage of the life cycle.

Figure 9.8 shows the implication of using the terry fabric manufacturing data in place of prefold manufacture. *Figure 9.8* shows that the system is sensitive to the prefold manufacturing data and suggests that the study would benefit to further work in this area.

Figure 9.8 Fabric production sensitivity

9.4.2 Aquatic toxicity

The methodology for fresh water aquatic ecotoxicity is not well developed and does not include characterisation factors for many detergent chemicals that are likely to pass through waste water treatment works unchanged. Work conducted by Procter and Gamble and Leiden University (Jeroen Guinee and Arjan de Koning) suggest that the toxicity loading that would arise per wash would amount to 2.19 kg 1,4-dichlorobenzene eq (DCBeq) per laundry wash and 1.49 1,4-dichlorobenzene eq (DCBeq) per home wash. This would increase the aquatic toxicity impact value to over 100 kg 1,4-dichlorobenzene equivalents for the commercial laundry system. This is a significant increase in this impact burden. The new characterisation factors that have been developed by CML are to be published later this year.

9.5 Age of data

The data used in the study are considered a reasonable reflection of nappy use in 2001-2002. The data reflects post 1990 technology, and includes data specific for 2001-2002. All inventories for flows identified as significant in the impact assessment are considered representative of 2001. In the main, materials production, manufacturing and nappy use have been defined using data describing activities in the study year.

9.6 Retail and consumer transport – data and allocation

Due to the lack of data regarding retail and consumer transport, assumptions and estimates have been made regarding retail outlet energy use and transport to and from retail outlets. These areas have most significance for the disposable nappy system. Allocation was required to allocate retail energy use and consumer transport of nappies home. Although we believe the data and allocations to be reasonable, the data may not be representative of the UK situation as a whole.

9.7 Data quality

The quality of the data with regard to consumer use characteristics (includes number of changes) and disposable manufacturing and disposable material manufacturing are considered to be very good. There are some concerns with regard to tumble drying; washing machine performance; and reusable nappy manufacture that results in a high level of uncertainty associated with the reusable nappy systems. Though individually the reusable manufacturing data sets are considered of good quality they can not be considered to be representative of all reusable nappies.

The systems assessed, including the sensitivities, provide a robust indication as to the scale of the potential impacts associated with the nappy systems.

9.8 Functional unit

The function that was deemed appropriate to the goals of the study was defined as *"the use of nappies during the first 2.5 years of a child's life"*. This functional unit was agreed by the Project Advisory Board early on in the study.

The user surveys commissioned by the Environment Agency supported the use of 2.5 years as a functional unit.

9.9 Normalisation

The individual impact results determined in the characterisation and classification steps above are difficult to compare and to interpret because of their differing orders of magnitude. Normalisation makes the impact assessment results for each system more meaningful, by relating them to the total emissions or extractions in a certain area over a given period of time. One method would be to compare the burdens for nappy use with the impact profile for UK households in the study year. However, these figures are not available, so total European annual effect scores for 1995 (total impact values for Europe) (Hujbregts *et al.2002*) have been used for the purpose of this study. Shown in *Figure 9.9* to *Figure 9.11* are the impact burdens for the whole life cycle as a percentage of the European impact burden.

If we accept the utility of normalised impacts, then the figures identify resource consumption of the three systems as being the most significant burden, in terms of scale of contribution. However this would change if the aquatic toxicity of detergent chemicals was confirmed, aquatic toxicity would become the most significant impact for the reusable systems, if the utility of normalisation is accepted.

The abiotic resource depletion impact burden is predominantly associated with the extraction of oil, gas and coal reserves. For the reusable systems, this impact is associated with energy consumption in the care of nappies. For the disposable system, it is associated with energy and fossil resource consumption associated with the production of polymers. This highlights the significance of care characteristics for reusables and change frequency for disposables. For the commercial laundry there is less potential variability in care.

Figure 9.9 Normalisation chart for disposable nappies

The chart's scale represents the contribution of one child's use of nappies over 2.5 years to total European impacts in 1995.

Figure 9.10 Normalisation chart for reusable nappy - home laundered

The chart's scale represents the contribution of one child's use of nappies over 2.5 years to total European impacts in 1995.

Figure 9.11 Normalisation chart for reusable nappy - commercial laundry

The chart's scale represents the contribution of one child's use of nappies over 2.5 years to total European impacts in 1995.

10 Interpretation and conclusions

There is no significant difference between any of the environmental impacts of the disposable, home use reusable and commercial laundry systems that were assessed. None of the systems studied is more or less environmentally preferable.

The following environmental impacts were agreed by the project board as those to be assessed in the study:

- global warming;
- ozone depletion
- summer smog formation (photo-oxidant formation);
- depletion of non-renewable reserves (depletion of abiotic resources);
- nutrient water pollution (eutrophication);
- acidification;
- human toxicity; and
- aquatic and terrestrial toxicity measures.

The impact burdens for each impact category have been normalised using the average impact burden across the three systems (the average, therefore, has a value of 1). *Figure 10.1* and show the similarity between the systems across all these impact categories using the impact ranges that result from the sensitivity analyses conducted. The variation in impact resulting from the sensitivity analysis is shown as a range for each impact. The analysis does not alter the overall conclusion.

For all three systems, the major impact areas, in terms of scale of contribution, have been identified as non-renewable resource depletion, acidification and global warming.

Although the impacts are very similar, the life cycle stages that are the main source for these impacts are different for each system. For the disposable nappy system, the main sources of environmental impact are raw material production and conversion of these materials into disposable nappy components, for example, fluff pulp and super absorbent polymer.

For the home laundered nappy system, the main source of environmental impact is the generation of the electricity used in washing and drying the nappies. For the commercial laundry system, the main sources of environmental impact are the fuels and electricity consumed by laundry activities.

For all three systems the impacts from waste management do not contribute substantially to the overall totals, although the proportion contributed by waste management is greater for the disposable nappies system than for the two reusable systems.

Global warming and non-renewable resource depletion impacts, over the 2.5 years for which a child is assumed to be using nappies, are comparable with driving a car between 1300 and 2200 miles.

In the UK, there are over 20 million cars on the road. Consequently, the wearing of nappies by children in the UK in one year results in a global warming and non renewable resource depletion impact equivalent to the consumption and emissions of 98,600 cars each driven an average 12,000 miles.

The results of the study suggest that the focus for improving the environmental performance of disposable nappies should be on the disposable nappy manufacturers and their suppliers whereas, with reusable nappies, it is the user who can achieve the most environmental gain through energy efficiency drives in the home:

- disposable nappy manufacturers should focus on weight reduction and improvements in materials manufacturing; and
- reusable users should focus on reducing energy consumed in washing and drying.

Figure 10.1 Sensitivity analysis of the three systems (normalised using average impact value for all systems)

Figure 10.2 Sensitivity analysis of the three systems (normalised using average (impact value for all systems)

10.1 Recommendations for further work

The study reports on the performance of the dominant nappy systems in use in 2001-2002. The study does not address what future developments may take place in disposable or reusable nappy systems. However, the study has been supported by a stakeholder group representing the interested parties and is the most comprehensive, independent study of its kind. Therefore, if products which were not studied become dominant in the market, or new products are developed, or changes are made to the existing dominant products which significantly reduce their impacts, then this study should be used as the basis for any further studies comparing the impacts of different types of disposable or reusable nappies.

Although not critical to the conclusions of the work, there are a number of areas where the study would benefit from further analysis and development. These areas were tested through sensitivity analysis in order to determine their significance.

The aquatic toxicity impact assessment method is a developing approach. As further research is published, a more accurate assessment will be possible.

The study could be improved with more data sets for the manufacture of cloth nappies. However, this element of the life cycle is not the main source of environmental impact for the reusable systems. The surveys conducted to determine consumer behaviour provided essential data relating to the use of nappies and were invaluable to the study. However, the amount of analysis and quality of the results might be improved with a larger sample and by refining the questions.

For the disposable nappy system, assumptions about excreta generation and its disposal have a significant effect on the ozone depletion impact. This is believed to be overestimated due to the allocation of emissions of CFCs from landfill on the basis of input mass, and not on the composition of the waste.

There was limited amount of data regarding the quantities of excreta that are generated by children. Further research in this area may increase the precision of the study.

Annex B

Impact Assessment Method (Includes Characterisation Factors)

Introduction

Extracted From Simapro

Name CML 2 baseline 2000 ERM Correction Acidification: NOx attributed a CF factor

Comment This method is an update from the CML 1992 method. This version is based on the spreadsheet version 2.02 (September 2001) as published on the CML web site and replaces the preliminary version.

The CML 2 baseline method elaborates the problem-oriented (midpoint) approach. The CML Guide provides a list of impact assessment categories grouped into A: Obligatory impact categories (Category indicators used in most LCAs) B: Additional impact categories (operational indicators exist, but are not often included in LCA studies)

C: Other impact categories (no operational indicators available, therefore impossible to include quantitatively in LCA)

In case several methods are available for obligatory impact categories, a baseline indicator is selected, based on the principle of best available practice. These baseline indicators are category indicators at "mid-point level" (problem oriented approach)". Baseline indicators are recommended for simplified studies. The guide provides guidelines for inclusion of other methods and impact category indicators in case of detailed studies and extended studies.

Only baseline indicators are available in the CML method in SimaPro (based on CML Excel spreadsheet with characterisation and normalisation factors). In general, these indicators do not deviate from the ones in the spreadsheet. In case the spreadsheet contained synonyms of substance names already available in the substance list of the SimaPro database, the existing names are used. A distinction is made for emissions to agricultural soil and industrial soil, indicated with respectively (agr.) or (ind.) behind substance names emitted to soil. Emissions to seawater are indicated with (sea), while emissions to fresh water have no addition behind their substance name (we assume that all emissions to water in existing process records are emissions to fresh water).

Depletion of abiotic resources

This impact category indicator is related to extraction of minerals and fossil fuels due to inputs in the system. The Abiotic Depletion Factor (ADF) is determined for each extraction of minerals and fossil fuels (kg antimony equivalents/kg extraction) based on concentration reserves and rate of deaccumulation.

Climate change

The characterisation model as developed by the Intergovernmental Panel on Climate Change (IPCC) is selected for development of characterisation factors. Factors are expressed as Global Warming Potential for time horizon 100 years (GWP100), in kg carbon dioxide/kg emission.

Stratospheric Ozone depletion

The characterisation model is developed by the World Meteorological Organisation (WMO) and defines ozone depletion potential of different gasses (kg CFC-11 equivalent/ kg emission).

Human toxicity

Characterisation factors, expressed as Human Toxicity Potentials (HTP), are calculated with USES-LCA, describing fate, exposure and effects of toxic substances for an infinite time horizon. For each toxic substance HTP's are expressed as 1,4-dichlorobenzene equivalents/ kg emission.

Fresh-water aquatic eco-toxicity

Eco-toxicity Potential (FAETP) are calculated with USES-LCA, describing fate, exposure and effects of toxic substances. Characterisation factors are expressed as 1,4-dichlorobenzene equivalents/ kg emission.

Marine aquatic ecotoxicity

Marine eco-toxicity refers to impacts of toxic substances on marine ecosystems (see description fresh water toxicity).

Terrestrial ecotoxicity

This category refers to impacts of toxic substances on terrestrial ecosystems (see description fresh water toxicity).

Photo-oxidant formation

Photochemical Ozone Creation Potential (POCP) (also known as summer smog) for emission of substances to air is calculated with the UNECE Trajectory model (including fate), and expressed in kg ethylene equivalents/kg emission. Acidification Acidification Potentials (AP) is expressed as kg SO2 equivalents/ kg emission.

Eutrophication

Nutrification potential (NP) is based on the stoichiometric procedure of Heijungs (1992), and expressed as kg PO4 equivalents/ kg emission. Normalisation For each baseline indicator, normalisation scores are calculated for the reference situations: the world in 1990, Europe in 1995 and the Netherlands in 1997. Normalisation data are described in the report: Huijbregts et al LCA normalisation data for the Netherlands (1997/1998), Western Europe (1995) and the World (1990 and 1995).

Grouping and weighting

Grouping and weighting are considered to be optional step. No baseline recommended rules or values are given for these steps. Based on the reports: "Life Cycle Assessment. An operational Guide to ISO Standards" Centre of Environmental Science (CML), Leiden University, the Netherlands. Download from

http://www.leidenuniv.nl/cml/lca2/index.html.

May 01 Characterisation for sum parameters metals added. October 2001 Version 2.02 update.

1 Introduction

1.1 General

I have reviewed the study Life Cycle Assessment of Disposable and Reusable Nappies, dated June 2004, prepared by Environmental Resources Management (ERM) for the Environment Agency in U.K. [1]. This review is undertaken for the Environment Agency.

1.2 Goal and scope of this critical review

1.2.1 International standards ISO 14040 - 14043

The form for a critical review or peer review is described in the international standard ISO 14040 [2]. Specific advice is also given in the standards ISO 14041 (Goal and scope definition and inventory analysis) [3], ISO 14042 (Life cycle impact assessment) [4] and ISO 14043 (Life cycle interpretation) [5]. According to the ISO 14040 [1] the critical review process shall ensure that:

- the methods used to carry out the LCA are consistence with this International Standard;
- the methods used to carry out the LCA are scientifically and technically valid;
- the data used are appropriate and reasonable in relation to the goal of the study;
- the interpretations reflect the limitations identified and the goal of the study;
- the study report is transparent and consistent.

The ISO 14040 gives alternatives to carry out the critical review. This review is an External Expert Review, that has do be carried out by an external expert, independent of the LCA study.

1.2.2 The requirements on this critical review

The ISO 14040 [2] states that the scope and type of critical review desired shall be defined in the scope phase of an LCA study. The goal and scope for this particular study is defined in the Section 3.10 in the report:

- *for the goal and scope:*
 - ensure that the scope of the study is consistent with the goal of the study, and that both are consistent with ISO 14041; and
 - prepare a review statement on the goal and scope. This review statement will be included in the final report and detail ERM's responses to the review.
- *for the inventory*:
 - review the inventory for transparency and consistency with the goal and scope and with ISO14041;
 - check data validation and that the data used are consistent with the system boundaries. It is unreasonable to expect the reviewer to check data and calculations beyond a small sample; and

- prepare a review statement.
- *for the impact assessment:*
 - review the impact assessment for appropriateness and conformity to ISO14042; and
 - prepare a review statement.
- *for the interpretation*:
 - review the conclusions of the study for appropriateness and conformity with the goal and scope of the study; and
 - prepare a review statement.
- *for the draft final report:*
 - review the draft final report for consistency with reporting guidelines in ISO 14040 and check that recommendations made in previous review statements have been addressed adequately; and
 - prepare a review statement including consistency of the study and international standards, scientific and technical validity, transparency and relation between interpretation, limitations and goal.

1.3 The review process

The work with the review has been undertaken according to the following:

- On June 18 I had a meeting with Environment Agency (Terry Coleman) and ERM (Michael Collins and Simon Aumônier) in London. The project was presented and the project circumstances were explained. I received an older draft version of the report (dated February 2004) for general information; ERM still had to update some of the modelling.
- On the 30 June I received an updated version of the report. This is the version that has been reviewed.
- A draft of the review statement was sent to Environment Agency (Terry Coleman) on July 15 for comments.
- The final version of the review statement was sent to Environment Agency on August 1.

I have also received an earlier review of the Goal and Scope stage, prepared by Göran Finnveden and Anna Björklund [6]. That review considered only the goal and scope stage of the study, and parts of the goals and scope have been changed since then. I have reused some of their remarks in the review of the goal and scope, where applicable.

2 Critical review statement

In general the report is extensive and written in clear and accessible language. The report describes the work adequately. The international standards in ISO 14040, ISO 14041, ISO 14042 and ISO 14043 has been adequately followed. However, the report needs some improvements and clarification. I have very few criticisms about how the work has been conducted. Most of my remarks concern how the work, and different assumptions and choices made during the work, have been presented in the report.

In ISO 14040 [2] special attention is given to comparative assertions, where different products are compared with each other. The extensive and demanding ISO 14040 guidelines for comparative assertions have been following adequately.

2.1 Goal and scope

2.1.1 Goal

The ISO 14040 [2] comments that since the standard does not specify requirements on the goals or uses of LCA, a critical review can neither verify nor validate the goals that are chosen for an LCA, or the uses to which LCA results are put.

The goal of the study is in general clearly defined and consistent with the intended application. I have the following remarks:

• The goal could be further specified by noting that the study is concerned with children's nappies use in 2001 - 2002.

PRACTITIONER'S RESPONSE: The reference to the time period has been added.

• One of the part goals or objectives has been "*to compare the results of the study with other key life cycle studies in this area and to identify the main reasons for any significant differences*". Such comparison has not been presented in report. In Chapter 1 of the report, there is a short overview of previous studies used as input to the study. The general conclusion of the overview is that the previous studies have been limited, insufficient, and not considered the latest developments in LCA methodology. This can be a motive for amending the goal and scope, and to delete this sub-goal from the goal and scope section.

PRACTITIONER'S RESPONSE: A note has been added to the report: 'This objective was considered superfluous due to the developments in LCA methodology, with nappies themselves and because the study is UK specific.'

2.1.2 Scope

The scope of the study is generally clearly defined and consistent with the intended application. I have the following remarks.

Functional unit

The choice of functional unit ("*the use of nappies during the first two and a half years of a child's life"*) is adequate, but can be clarified. It should be clarified that there is an U.K. child, and that the use of nappies is referred to 2001 - 2002.

PRACTITIONER'S RESPONSE: This has been done.

Nevertheless, the work with quantifying the functional unit, and to avoid uncertain assumptions about nappy use, is exemplary.

System boundaries

The system boundaries are defined according to ISO 14041 [3], but should be further specified.

Beside the ISO standard there has since long been a scientific discussion about system boundaries in LCA. For example, Guinée [7] sets up the following types of system boundaries:

- 1. Boundaries between the product system and the natural environment
- 2. Boundaries between significant and insignificant processes
- 3. Boundaries between the product system under study and other product systems (allocation).

PRACTITIONER'S RESPONSE: We would like to reiterate that the study is consistent with the International Standard for LCA, this is agreed by the reviewer. System boundaries can always be better defined. To this end, we have amended the report to address the comments below.

Also time can be added as a fourth system boundary [6].

Since ISO 14041 [3] states that "any decisions to omit life cycle stages, processes or inputs/outputs shall be clearly stated and justified" I suggest that the system boundaries be better defined according to the following.

• The first type of system boundary is relevant when modelling agriculture and forestry. For example, if the parents choose reusable cloth nappies, this will result in alternative use of the forest, be it for alternative products, alternative crops, recreational use etc., and if disposable nappies are used this would lead to alternative use of cotton fields. These secondary affects, though likely to be significant, are generally ignored in LCA studies. Though it is common practice to ignore, I believe the report should state that they have been ignored. This should be added to the goal and scope and be reiterated in the interpretation section.

PRACTITIONER'S RESPONSE: We have added text to this effect.

'This study addressed flows to and from the environment for each life cycle stage. However, the study excluded the environmental implications of land occupation and use. For example, the implications of alternative land use and the affects of land use changes were excluded. The systems assessed were considered to be steady state.'

- The second type of system boundary (between significant and insignificant processes) are discussed and considered adequately in the report.
- About the third type of system boundary (allocation) some comments can be made. Section 3.3 explains that "*inputs and outputs of the inter-related product systems have been apportioned in a manner that reflects the underlying physical relationships between them*". However, other allocation principles have been used in the study, e.g., energy consumption by the retail sector has been apportioned according to the monetary value of sales. This is allowed according to ISO 14041 [3], when physical relationship alone cannot be established or used as basis for the allocation. Section 3.3 in the report should include a statement that economic value is also used as the allocation basis.

PRACTITIONER'S RESPONSE: This has been done.

• The fourth type of system boundary (time) is relevant for landfilling of waste. A cutoff time of 100 years is used for gas emissions in the software tool WISARD that has been used in the study to model the waste management in the study. I would question whether 100 years is reasonable considering that waste may not be fully degraded by this point in time. I accept that WISARD was peer reviewed and that it was developed reflecting UK landfills and best scientific understanding. I suggest that the issue of system boundary compatibility is discussed within the report and that the 100-year cut off be assessed for significance and as to whether it is reasonable.

PRACTITIONER'S RESPONSE: A description of *WISARD* has been added to the report. With regard to time boundary, the *WISARD* tool uses a 100 year cut off for landfill gas and a 500 year cut off for leachate. These periods were determined so as to account for the majority of the emissions. The landfill model assumes 23% fugitive emission of landfill gas and 77% combustion (41% flare and 36% energy recovery) of landfill gas over its life. When developing the life cycle inventory model for landfill, the issue of time frame was studied as a sensitivity. The simulated landfill models, in the *WISARD* R&D report for landfill, all result in gas generation approaching zero m³/hr after 60 years, from highs of between 1000 and 6000 m³/hr.

Criteria for inclusion and exclusion

The inclusions and exclusions in Section 3.4 are in accordance with the scope of the international standard ISO 14041 [3]. Often the resource depletion and environmental impact connected to construction of equipment and buildings are negligible compared to the resource depletion and environmental impact during the operational phase. This is especially true for energy-intensive processes. In this study the energy-intensive studies are dominant. Also workforce burdens are usually excluded in LCA studies, often because there is no generally accepted method to handle these burdens.

The report presents assumptions as to how excreta are disposed of or treated for disposable nappies and home laundered reusable nappies (section 3.4.3). However, nothing is mentioned about excreta from commercial laundered reusable nappies. It is not obvious that the excreta on the commercial laundered nappies are handled the same way as the home laundered.

PRACTITIONER'S RESPONSE: Text has been added to the report stating that excreta has been handled in the same way.

Other points

In Section 3.6.6 it is declared that "*the foreground and background systems have been specified clearly in the report*". Such specification is not found in the report. This also raises questions when it in the report is referred to the foreground and background system.

PRACTITIONER'S RESPONSE: mention of the terms foreground and background have been removed and more detailed descriptions added.

Section 3.7 declares some important flows, which are presented more in detail. I interpret that the list is the important inputs and outputs to/from the studied system. Solid waste generation is included in the list. However, if treatment of solid waste is handled within the system boundary, then the solid waste is an internal flow and does not leave the system. It is therefore not something that should be reported in the inventory analysis, but it is an important internal flow. Whether solid waste is flow leaving the system or an internal flow should be clarified. In the latter case it should not be listed in section 3.7, but can be mentioned as an important internal flow.

PRACTITIONER'S RESPONSE: solid waste as been labelled as an internal flow.

The software WISARD has been used for modelling the waste management in the system. Since waste management is an important part of the system the report should include a goal and scope description of WISARD (in an appendix).

PRACTITIONER'S RESPONSE: Documentation relating to *WISARD* has been added as an Annex.

2.2 Inventory

I have in general found that the inventory is transparent and consistent with the goal and scope and with ISO 14041 [3]. Data have been collected from different sources, and my judgement is that the best available data have been used. As far as possible data have been gathered from scientific measurements (surveys), validated LCI databases (e.g. EDANA, BUWAL, WISARD) or literature. I have also checked a small sample of data and found that appropriate data have been chosen and used. All data and all calculations seem reasonable - with a few exceptions that are commented on below. Uncertainties in data have been subjected to sensitivity analysis.

I have found the following:

- As already mentioned above, I find the presentation of waste flows a little confusing. According to ISO 14040 "*Inventory analysis involves data collection and calculation procedures to quantify relevant inputs and outputs of a product system*". I consider the waste management system to be a part of the product system. Consequently waste flows should not be reported as outputs (as in Table 4.1).
- •

PRACTITIONER'S RESPONSE: solid waste as been labelled as an internal flow.

- There is also some lack of clarity about the treatment of waste from manufacture, which should be clarified. :
 - Waste from manufacture is recorded for disposable nappies, but not for reusable. Can these wastes be neglected?
 - Details of the management of manufacturing waste should be given. For disposable nappies, the report describes how the municipal solid waste is treated, but not how manufacturing wastes are managed.

PRACTITIONER'S RESPONSE: Text and data relating to solid waste from the both disposable and reusable nappy manufacture has been added to the report.

• The WISARD software is used to model the waste disposal. In the modelling some key assumptions have been made, e.g. how is the energy recovered (heat or electricity) in incineration, is gas recovered from the landfill and how is it utilised, how is the leachate from the landfill treated. These assumptions are necessary for the transparency. These assumptions should be clearly stated.

•

PRACTITIONER'S RESPONSE: This information has been added to *Section 4.6*.

• The description of different unit processes is rather poor. According to ISO 14041 Clause 8, the study report should include qualitative and quantitative description of unit processes. The understanding of the processes, and their environmental impact, in manufacture, retail, use and disposal can increase if the different processes are better described. However, I am aware that a more detailed description can have both advantages and disadvantages. The advantages are that the life cycle is better understood, and the transparency is increased. The disadvantages are that the report will be more extensive and perhaps more difficult to read. I suggest that at least a summarised description be put in an Appendix.

PRACTITIONER'S RESPONSE: Additional process description of disposable nappy manufacture, cotton production and reusable nappy production has been added to the relevant sections. Though further description maybe of benefit, we feel that the references and the inventory data provided are comprehensive as to what has been modelled with regard to inputs and outputs from processes.

• In Chapter 7 the inventory results are presented in tables for the main flows. I have noted that there is some inconsistency for the BOD and COD results. Both BOD and

COD are measures of the organic content in wastewater (leachate from landfill is one type of wastewater). Usually BOD and COD are measured in different ways: BOD by biological oxidation and COD by chemical oxidation. COD gives a measure of the total (at least the total chemically oxidizable content), and BOD gives a measure of how much is biologically oxidizable. Thus the BOD content is usually a part of the COD content. For all common wastewaters the ratio BOD/COD ≤ 1 . When the inventory analysis is presented is should be expected that BOD/COD ≤ 1 . COD for leachate water from landfill (disposable nappy system) are reported to be = 0, while the BOD is 0,84 kg (Table 7.1), 0,613 kg (Table 7.2) or 0,013 kg (Table 7.3). Although neither BOD nor COD are strictly inventory flows, the COD = 0 from waste management should be clarified.

•

PRACTITIONER'S RESPONSE: We agree that the COD number is erroneous and this has been noted in the inventory analysis section and is addressed in the sensitivity analysis section.

2.3 Environmental impact

I have found that the impact assessment is appropriate and conforms to ISO 14042. The selection of impact categories, category indicators and characterisation models has been described.

The characterisation model used in the study is CML version 2.02 updated in September 2001. The CML model is internationally accepted. I feel it necessary to point out that updated CML characterisation factors were published earlier this year [8]. I would therefore suggest that the report is either revised using the new characterisation factors, or an assessment of significance is conducted. The report has stated the impact assessment method used, and has included the characterisation factors used within report, as required by ISO. It is my understanding that the changes that have been made affect the global warming and ozone depletion impact categories.

PRACTITIONER'S RESPONSE: We agree that amendments have been made by CML and that these were not incorporated into our assessment. The characterisation factors we have used are those published in the Handbook on Life Cycle, Final editor Jeroen B. Guinee, 2002. However, we have compared the versions, the one we have used and the most recent CML version with regard to the implications for this study and found the changes to be insignificant. No difference was found for ozone depletion. The implications for global warming would be a 2% increase in GHG emission for disposable nappy systems and a 1% increase in GHG emission for the home laundered system.

I agree with the statements about human toxicity and aquatic and terrestrial eco-toxicity. The accuracy of these impact models is questionable, and the results from these impact categories should be interpreted very cautiously, as stated in the report.

The impact results of the study have been normalised. The environmental impact from U.K. nappies is put in relation to total European impacts. This normalisation procedure is according to the ISO standard.

2.4 Interpretation

The study has been adequately interpreted according to the international standard ISO 14043. According to this standard the objectives with the interpretation are to analyse results, reach conclusions, explain limitations and provide recommendations based on the findings from the study. This has been done in an exemplary manner.

2.5 Final report

The requirements for an LCA report are given in ISO 14040 [2]. In general the reporting accords with the standard. However, the report has some omissions. There are cases where data, methods, assumptions and limitations are not totally transparent and/or are not presented in sufficient detail to allow the reader to comprehend the complexities and trade-offs inherent in the LCA study. Those cases have all been mentioned and discussed above. In sections 2.1 - 2.4 in this review report, I have made some comments and suggestions for revising and completing the report. These remarks are particularly connected to the description and definition of system boundaries.

Earlier, a review has been conducted for the Goal and Scope stage [6]. I have found that some of the remarks given in that review do not appear to have been considered. I have taken up those, which are relevant, for example:

- the time aspects should be defined in the goal and scope
- completing the allocation discussion, how to allocate when "underlying physical relationships" is not possible.
- the cut-off time for the landfill should be clarified
- solid waste generation is noted as an output, although it is an internal flow.

Moreover, I have some further comments concerning the reporting:

• The references should be given more clearly. The references are clear enough for a skilled LCA practitioner. However, because the study is also for a wider audience it is recommended that the references be given more clearly so that also the intended audience can identify and search the relevant sources. This is particularly important for the data sources mentioned in Tables 4.4 (new version Table 4.5), 5.12 (new version Table 5.9) and 6.8.

PRACTITIONER'S RESPONSE: More detailed references have been included.

• The following sentence in Section 3.5 "*All assumption will be recorded and reported in the final report*" is unclear. All assumptions should be recorded and reported in the version that is critically reviewed.

PRACTITIONER'S RESPONSE: Agree and report has been amended.

• References to data sources in the inventory are not clear. For disposable nappies the data sources for e.g. manufacture is given in Table 4.4, while the manufacture is mentioned in Section 4.1 and Table 4.1 without references to data sources. This criticism is also valid for Chapter 5 and 6 where the data sources are first shown at the end of the chapter.

PRACTITIONER'S RESPONSE: Though the reviewer considers this less helpful, the presentation in a summary table of all flows and data sources in our view aids rapid appreciation of the systems assessed and how they have been modelled. To this end we have included cross references in the report.

Some headings are a little confusing. Chapter 4, 5 and 6 is named Inventory analysis (respectively for each nappy system). Then Chapter 7 is also named Inventory analysis (with secondary headings for each nappy system). The naming of these should be revised.

PRACTITIONER'S RESPONSE: Titles have been amended.

• Table 5.9 seems to be a copy of Table 1.11 except for Nitrogen and Water. Table 5.10 seems to be a copy of Table 1.12 except for contents of "Other". Table 5.11 seems to be an identical copy of Table 1.9. The purposes of the differences between the tables in Chapter 5 and Chapter 1 should be explained. I also think it is unnecessary to have the tables duplicated or almost duplicated. It would be sufficient to refer to the tables in Chapter 1 and explain and justify the differences.

PRACTITIONER'S RESPONSE: The duplicates were an error and have been removed.

• The name of Chapter 9 should be changed. The chapter does not touch the interpretation. The normalisation section (9.9) may be moved to the impact assessment chapter (Chapter 8). In ISO 14042 the normalisation is a part of the environmental impact assessment.

PRACTITIONER'S RESPONSE: Titles have been changed.

• Appendix A and Appendix B should change places. It is more logical to have the Inventory before the impact assessment.

PRACTITIONER'S RESPONSE: Agree.

2.6 Conclusions

This critical review can be summarised as the following:

- the methods used to carry out the LCA are consistence with this International Standard;
- the methods used to carry out the LCA are scientifically and technically valid;
- the data used are in general appropriate and reasonable in relation to the goal of the study;
- the interpretations reflect the limitations identified and the goal of the study;

- the study report is <u>not</u> always transparent and consistent. The report should be revised to deal the aspects identified in this review.

Annex D

WISARD

1. Foreword

The purpose of this document is to

- gather all information to be entered by the user,
- clearly state the assumptions (allocation rules, end of life of buildings) that have been made to finish the system description,
- explain how environment and economic simulations are carried out.

Background

The Environment Agency's Life Cycle Research programme was started four years ago. The aim of the programme is to provide an objective basis for the. comparison of waste management strategies and of options for individual waste types and to give waste managers the capability to assess this themselves. The programme investigates the environmental inputs and outputs, both energy and raw materials, and the related impacts of waste management options from cradle to / grave. !

To this end the programme has explored the application of Life Cycle Assessment (LCA) techniques to waste management. LCA techniques provide an objective basis to improve the decision making process for waste managers and planners in regard to managing their waste. LCA, combined with an evaluation of associated internal costs, is increasingly being used to determine best practice with industry , consistent with the demands of meeting BA TNEEC.

Programme Direction

The Environment Agency's programme includes the following five phases: Phase

- 1. Methodological guidelines for inventory analysis
- 2. Data collection and inventory analysis
 - a) Impact assessment
 - b) Damage cost valuation
- 4. Software development
- 5. Decision tool applications

Allocation Rules for WISARD

Allocation rules for *WISARD* were defined during the early stages of the Environment Agency's programme. Phases one and two of the programme should have already defined the allocation rules and checked that these are correct. Ensuring that the allocation rules for the programme are consistent was part of another process and not specifically part of the development of the tool. Allocation rules used throughout WISARD are described in this manual.

1.1 Data Transparency

Information pages for data sets in *WISARD have* been compiled and are included in the Appendices of this report.

2. Methodology

1.2 Scope of the tool

The purpose of the software (*WISARD* 3.3) is to quantify the environmental impact of collecting and processing municipal solid waste using life cycle assessment techniques.

The software tool has been designed to respond to the following questions:

- What impact do the various stages of municipal solid waste management have and what is their relative importance?
- What are the technical parameters that influence this and what actions can be taken as levers to reduce the impact of waste processing?
- How do alternative or "future" scenarios compare with reference scenario?

Figure 1 shows the scope of the *WISARD* program and summarises the various stages included in the analysis of the system. Waste is either placed on the kerb in a container or sack for collection or brought to a designated location for example, a recycling bank located at a shopping centre. The waste is collected, transported and either recovered or disposed of. The user must also describe reprocessing for those materials that have been recovered. Chemicals, consumables, energy and fuels used for the total system are also considered in *WISARD*.

WISARD has been developed following the guidelines described in the ISO 140401 series of standards.

1.3 Functional Unit

The collection and treatment of municipal solid waste generated by a local community (or a group of local communities) for a period of one year. The purpose of defining this functional unit is to compare alternative scenarios using the same service provided to the community as a starting point.

I ISO IS 14040, "Environmental Management- Life Cycle Assessment- Principles and framework", March 1997.

Figure 1: Scope of the WISARD tool

The functional unit includes waste generated over a year to enable possible seasonal variations in quantity and quality (occurring as a result of tourist flows) to be taken into account.

System boundaries/space and time

The tool takes into account all the stages in the management and processing of the waste, from the household front door through to the technically controlled disposal or recovery of the waste.

The upstream limit of the system is the "resource", represented by the refuse produced. The tool does not take into account either the production or use of the consumable items which will become this resource after use. This means that the analysis cannot be considered as being from "the cradle to the grave", as the departure point of the system is the refuse produced.

The model takes into account household waste and CA/bring system wastes. Commercial waste can be included provided its composition is similar to that of household waste.

Important note: the estimation of the waste quantity should not take into account the waste being home composted, as the treatment of homecomposted waste (i.e. digestion process and emission to atmosphere) is not yet part of the tool. Management of municipal solid waste is divided into two major sections: collection and processing.

Collection

The tool takes the following elements into account:

- production, use and end of useful life of the skips, containers and collection sacks;
- use of the collection vehicles;
- production, maintenance and end of useful life of the collection vehicles;
- collection at a transfer site or amenity tip. The construction, use or demolition of the site is taken into account; and
- transportation to a processing or recovery unit.

Collections are either door-to-door or brought by the individual. In the event of collections brought in by individuals, the possible use of private vehicles to firing the refuse to a terminal or amenity tip can also be taken into account.

For a given scenario, the resource in the form of refuse being the base definition, the user can define as many collection scenarios as he/she wishes.

Processing

The tool takes the following elements into account:

- Thermal treatment by incineration. Various process methods can be described for the atmospheric emissions (dust separation, dry, semidry or water treatments, specific, non- catalytic treatment of the nitrogen oxides, specific treatment of the dioxins and heavy metals by passing them over activated carbon). Likewise, various types of energy recovery can be taken into account. What happens to the solid by-products from the incineration, clinkers, residue from emission purification, scrap iron and aluminium waste is also taken into account (transportation, processing or recovery).
- Composting with sorting and possible recycling of glass, scrap iron, aluminium and -mixed plastics. Transportation and spreading of the compost produced are also taken into account.
- Anaerobic digestion with sorting and possible recycling of glass, scrap iron, aluminium and mixed plastics. The transportation and application of the refined product are also taken into account.
- Sorting and recycling of packaging, newspapers and magazines.

- Landfill with treatment of the landfill gas (flaring of furnace combustion) and the leached products (evaporation/incineration, treatment in purification stations on or off-site)

Construction, operation and end of the useful life (by demolition or covering over in the case of burial sites) of the sites are taken into account. Movement of site machinery is also taken into account using the combustion and consumption of the diesel.

In general only normal operation is taken into account for all the sites. For example, this excludes fires on the landfill sites and the burning of compost.

Time boundaries

The functional unit used in *WISARD* refers to municipal solid waste treatment over a period of one year.

In the case of collections and operations on some sites, such as sorting and incineration, transportation or processing dates correspond to the same period of a year, give or take a few days. The relative emissions into the atmosphere or water ~e place within the same period of time.

By contrast, emissions on other sites may be deferred by a few weeks (composting) or even by up to several decades, in the case of landfill.

In the latter case the system takes into account first the aerobic reactions and then the anaerobic reactions associated with the fermentation of rotting wastes, which produce landfill gas and leached products through the infiltration of rainwater.

The time boundary is set at the end of the landfill gas formation phase, in other words, 100 years after the waste has been deposited.

Appropriate Data

The choice of data used in *WISARD* should reflect the question being asked. For example, 'average' plant data maybe appropriate in modelling current situations, whereas "best practice" data should be used for examining future strategies.

Allocation rules

During data collection, methodological guidance was issued by a consultant to insure that all data collections were performed on a consistent basis.

So as to model waste treatments, additional allocation rules have been used. These are described in the sections to follow (8 to 17). It should be noted that the allocation principles are specific for the goal of the tool, especially considering the functional unit that has been chosen.

ECOBILAN-WM3.4r1

Avoided impacts

WISARD uses the avoided burden methodology as described in the ISO 140412 standards. The -avoided inputs and outputs used can be broken down into energy and materials. Each of these will be discussed in turn.

1.4 Modelling of Energy Recovery

WISARD calculates and assigns credits to those scenarios where landfill, incineration and -anaerobic digestion are producing energy from waste. This energy may be in the form of either electricity or steam production. For the steam production, the user has the option of using the default fuel source to generate an equivalent quantity of steam or alternatively, the user can describe the fuel source by modifying a disposal method to suit existing conditions.

For the avoided production of electricity, *WISARD* assumes that the fuel source would be 100% ~ coal. That is, it is the avoided use of marginal electricity as opposed to base load electricity.

1.5 Modelling of recycling

This is dependent on the recycled and virgin products

Some of the process paths allow all or some of the municipal solid waste to be treated and fulfil the function analysed. However, some treatment sites can also make provision for one or more -additional functions:

- production of materials reused by industry (recycling after sorting, recovery of bottom I ash, sorting of the composting or anaerobic digestion sites),
- production of organic changes (composting, anaerobic digestion),
- energy production (incineration, anaerobic digestion, landfilling).

To identify the appropriate avoided impacts, the user must consider the following questions

1. What is the composition of the material being recycled?

The composition of the material being recycled can be used to define the recovery path of

municipal solid packaging material. The path/s which are representative of the current situation .in the UK, or that in the near future, have been taken into account in WISARD with the ~ agreement with the relevant manufacturers.

2. What is the recycled material replacing (that is, by recycling this material what is it avoiding ~ the production of)?

ECOBILAN-WM3.4r1

2 ISO 14041 -"Environmental management -Life cycle assessment -Goal and scope definition and inventory analysis" October I 1998

The recycling/recovery paths that are currently used in France, or which may be used in the near future, have been taken into account within WISARD. The Ecobilan Group has obtained the appropriate permissions from the relevant manufacturers before using their data in the software.

- 3. What is the mass of material being avoided by recycling 1 kg of the same material?
- 4. 4. Which of the flows/Impacts are taken into account and which are not.

The answers to these questions are given in the table 'Description Of Recycling Modules For Various Categories Of Municipal solid Waste' in Section 0.

In some cases, however, (recycling of scrap metal, some paper and cardboard, glass bottle bank), the recycled material or the reused product replaces a mixture of new and recycled material. The question then arises of the impact of making the recycled material3 available in the replaced process route.

The methodology developed for the French Environment Agency (Ademe) as part of the project, relating to the creation of a database for the production of packaging materials, proposes the following distribution of the environmental impact between the refuse production path and its recycling path:

- transportation from the site of production of the refuse to a sorting centre for municipal solid waste (for example) is treated as "inevitable" transportation -one way or another, municipal solid waste has to be dealt with. It is ascribed to the production path of the refuse. Thus it can be considered that the stock of material drawn upon to obtain "secondary materials" is practically created.

- extraction of the scrap metal, old paper or broken glass from the stock, possible transportation of these to the processing site (crushing for some of the scrap metal, sorting and compaction of old paper, crushing and washing of the incineration residue), the treatment itself and then the transportation to the site of use in the form of "secondary materials" are attributed to their recycling path.

This is not the only possible distribution of the environmental costs, but it does have the advantage of being applicable to the five packaging materials (steel, aluminium, paper and

³ The same question arises when calculating the environmental cost of the recycled paper sack used during the collection, for example. In contrast, it does not arise in the case most commonly encountered in *WISA.RD*, where a recycled material

replaces a new material. In actual fact the objectives for this tool differ from those of the "Packaging Materials" database created by Ecobilan for Ademe (France) concerning the entire life cycle of the packaging. In this case the objectives are:

[.]to calculate the overall environmental cost of recycling a material, incorporating the gains due to the impacts avoided by the non-production of a substitute material. There is no requirement to distribute the cost of recycling among the waste and the recycled product.

ECOBILAN -WM3.4rl 8 jjl I]f

cardboard, plastics and glass). The same distribution was selected for this project, not only for the reason outlined above, but also with an eye to uniformity between the work carried out with *WISARD* in France.

1.6 Abnormal operations

Abnormal operations are outside the scope of the tool and have not been included. An example of an abnormal operation would be afire at a landfill.

WISARD limitations

It should be noted that while *WISARD* considers some environmental aspects, it does not address human or environmental safety, legal compliance issues or nuisance issues (e.g. litter, dust and visual amenities). *WISARD* is only one tool in the toolbox. There are other tools such as risk assessment and environmental impact assessments, which should be used for other functions such as assessing the safety of particular processes or the siting of particular waste handling or treatment plants.
